## 2.7

### **Key word factor ADZE**

#### **2.7.1 Definition**

*Two real functions are defined:*

```
DFC1=DEFI_FONCTION (  
NOM_PARA=' X',  
NOM_RESU=' Y',  
VALE= (0. , 10. , 4. , 14. , 6. , 16. ),  
PROL_DROITE=' LINEAIRE',  
PROL_GAUCHE=' LINEAIRE'  
)
```

```
DFC2=DEFI_FONCTION (  
NOM_PARA=' X',  
NOM_RESU=' Y',  
VALE= (5. , 25. , 7. , 27. , 8. , 28. ),
```

*PROL\_DROITE=' LINEAIRE',  
PROL\_GAUCHE=' LINEAIRE'  
)*

*One assembles these two functions, while overloading on the right.*

## **3**

### **Generation of a function by IMPR\_COURBE**

*One tests the possibility of IMPR\_COURBE of writing a function with the format “ORDERS”. The line of order generated by IMPR\_COURBE is carried out by making a INCLUDE in CONTINUATION; then, it is checked that one finds the values of the printed function.*

## 4

### **Summary of the results**

*This test validates the whole of the orders which create functions (DEFI\_FONCTION, IMPR\_COURBE, and in particular order CALC\_FONCTION).*

*The attributes of the functions there are tested: type of interpolation, prolongations,... as well as the values*

*interpolated or not for tablecloths and functions real or complex.*

*The only significant errors are raised on real applications (accélérogramme by example), where one has only values of nonregression.*

**VI.01.102 document**

**ZZZZ102 - To see accélérogramme and spectrum of oscillator**

**Summary:**

*This test concerns:*

*1) reading under various formats of a accélérogramme on an external file (LIRE\_FONCTION [U4.21.08]) and the test of the attributes of the function and the value max,*

*2) the checking of the calculation of the spectrum of oscillator by CALC\_FONCTION [U4.62.04] and of the value of*

*high frequency acceleration (> 35.5 Hz) according to the value max of the accélérogramme,*

*3) reading of a spectrum of oscillators in free format on an external file (LIRE\_FONCTION [U4.21.08]).*

*There are not grid or of model finite element and two modelings.*

***Problem of reference***

*Several reading of signals are to be realized:*

- reading of a accélérogramme not centered (maximum amplitudes  $> 0$  and  $< 0$  different) expressed in G (9.81 ms<sup>2</sup>) and research of the maximum amplitude,*
- calculation of the spectra of oscillator for a reduced damping = 0.01 (1%) with the options of calculation:*

-

*pseudo absolute acceleration and to find the acceleration of high frequency drive (F <sup>3</sup> 35.5 Hz),*

*- displacement*

*relative,*

- reading of a accélérogramme centered (LBEW: seism Length Beach East West) and seeks maximum amplitude,*
- calculation of the spectrum of oscillator in pseudo absolute acceleration,*
- reading of a spectrum of oscillator in free format.*

**2**

***Reference solution***

**DEFI\_GROUP [U4.12.03]**

**Summary:**

This test validates the various options of creation of groups of meshes (or nodes) by criteria **geometrical** in order DEFI\_GROUP [U4.12.03]:

- “SPHERE”
- “CYLINDER”
- “BAND”
- “FACE\_NORMALE”
- “ENV\_SPHERE”

· “ENV\_CYLINDRE”

· “PLANE”

### **Problem of reference**

y

C

B

has

With

has

X

It is about a square plate on side  $is = 10$ . and thickness  $T = 1$ .

**1.1**

### **Material properties**

$E = 1$ .

$\nu = 0.3$

**1.2**

### **Boundary conditions and loading**

The plate is embedded along side AB.

One has 7 loading cases for modeling A and 5 loading cases for modeling B.

Each loading case corresponds to the superposition of 2 loadings which are cancelled.

One of these loadings applies to a GROUP\_MA or a GROUP\_NO defined starting from a criterion geometrical in DEFI\_GROUP, the other, of opposed sign, applies to the GROUP\_MA or the GROUP\_NO

defined “in extension” (with the hand).

Modeling A uses a model “3D” in hull DKT.

Modeling B uses a model “D\_PLAN” in TRIA3.

The grids are the same ones.

## Summary of the results

The results are good: the groups calculated by order DEFI\_GROUP are well the groups waited.

Attention however with the fact that the test "3D" is actually a test on a plate in plan XOY: role of the 3rd co-ordinate in FORTRAN is thus not tested.

***ZZZZ111 - Validation of operator DEFI\_CABLE\_BP***

***Summary:***

***The goal of this case-test is to validate the operator DEFI\_CABLE\_BP [U4.23.06], who calculates the profiles of tension in the cables of prestressed of a structure of concrete, in accordance with the rules of the BPEL: those allow to take account of the losses of tension per contact between the cables and the concrete, by retreat with anchorings, by shrinking and creep of the concrete and relieving of steel, material constituting the cables.***

***The structure considered is a semi-cylindrical veil, containing in its thickness four cables of prestressed. The cables describe each one a half-circle in a horizontal plane, and thus traverse the veil over its length. Two cables have an eccentricity compared to the average radius of the veil.***

***The results obtained are validated by comparison with those theoretically awaited. Profiles of tension can be clarified analytically out of the zones where the losses by retreat apply to anchorings.***

### ***1 Problem of reference***

#### ***1.1 Geometry***

***The concrete veil has a semi-cylindrical form: the height is  $H = 10$  m and the average radius is worth  $R = 10$  Mr.***

***The thickness of the veil is worth  $E = 0,6$  Mr. the “average radius equivalent”, within the meaning of the BPEL on the section***

***vertical of the veil is worth thus  $rm = 0,283$  m, knowing that:***

$$rm = \frac{eH}{2(E + H)}$$

***(ref. BPEL 2.1, 5)***

***The cables describe each one a half-circle in a horizontal plane, and thus traverse the veil on its length. The dimensions of the plans containing the cables are:***

***for the cable n°1:  $z1 = 1$  m;***

***for the cable n°2:  $z2 = 3,5$  m;***

***for the cable n°3:  $z3 = 6$  m;***

***for the cable n°4:  $z4 = 8,5$  Mr.***

***Cables 3 and 4 have an eccentricity compared to the average radius of the veil, being worth respectively:***

***$ex3 = 0,05$  m;***

***$ex4 = 0,1$  Mr.***

***The surface of the cross-section of each cable is worth  $Its = 1,5.104$  m<sup>2</sup>.***

#### ***1.2 Properties of materials***

### ***1.2.1 Material concrete constituting the veil***

***Reference solution***

***2.1***

***Curvilinear X-coordinate and cumulated angular deviation***

***The cables describe each one a trajectory in the form of half-circle in a horizontal plane. In consequence, the curvilinear X-coordinate S and the cumulated angular deviation are expressed very simply:***

$$S = Rc$$

=

where  $Rc$  indicates the ray of the half-circle described by the cable, and the azimuth in cylindrical coordinates.

The values of reference for the tests are estimated using these expressions.

## 2.2

### Normal effort in the cables

One considers a cable describing a horizontal half-circle of  $Rc$  ray. The  $0$  locating azimuth is noted end of the zone where the losses of tension by retreat apply to the first anchoring;  $-0$  reference mark it

beginning of the zone where the losses of tension by retreat apply to the second anchoring.

Taking into account the preceding expressions of the curvilinear  $X$ -coordinate and angular deviation cumulated, the profile of tension along the cable can be parameterized by the azimuth, out of the zones where

apply the losses by retreat to anchorings:

$$F() = -F0(Xflu + xret)$$

**The values of reference for the tests are estimated using these expressions, which define one symmetrical profile of tension compared to the central node.**

**2.3**

**Index of projection**

**The projection of a node pertaining to the one of the cables on a mesh of the concrete veil gives place to the assignment of an index of projection IPROJ in accordance with the following rule:**

**Projection on a mesh triangle of nodes N1 tops, N2 and N3:**

**.**

***IPROJ = 0***

*if the projected point is inside the triangle;*

.

***IPROJ = 11, 12 or 13 if the projected point belongs respectively to the edge [N1; N2], [N2; N3] or [N3; N1];***

.

***IPROJ = 2***

*if there is coincidence of the point projected with a node top.*

***Projection on a mesh quadrangle of nodes N1 tops, N2 N3 and N4:***

.

***IPROJ = 0***

*if the projected point is inside the quadrangle;*

.

***IPROJ = 11, 12, 13 or 14 if the projected point belongs respectively to the edge [N1; N2], [N2; N3], [N3; N4] or [N4; N1];***

.

***IPROJ = 2***

*if there is coincidence of the point projected with a node top.*

***The values of reference for the tests are estimated by predicting the places of projection of the cables, taking into account their situation compared to the veil and provision of the meshes on this one.***

***2.4 Eccentricity***

*The eccentricity of a node pertaining to the one of the cables is defined as the distance from this node with*

*net concrete veil on which it is projected.*

*Seen in a horizontal plane, the trace of the mesh is a cord on the half-circle of ray  $R$ . One notes the angular sector covered by the mesh. The node of the cable, noted  $NC$ , is located on the half-circle of  $R_c$  ray. Its relative position compared to the mesh is located by the azimuth.*

$NC$

$R$

$R_c$

*The vector  $\cos$*

*;  $\sin$*

$2$

*$2$  is normal with the cord, which passes by the point  $(R; 0)$ .*

*The equation of the cord is thus  $\cos$*

*$X + \sin$*

*$y - R \cos$*

*$= 0$*

$2$

$2$

$2$

*The distance from a point on a line, in the plan, is given by:*

*$ax_0 + by + C$*

*$D =$*

*$0$*

*$a^2 + b^2$*

*where  $(x_0; y_0)$  is the co-ordinates of the point and  $ax+by+c=0$  is the equation of the right-hand side.*

*Node  $NC$  pertaining to the cable has as co-ordinates  $(R_c \cos; R_c \sin)$ . Its eccentricity by report/ratio with the mesh of the veil on which it is projected is thus worth:*

$exc = Rc \cos$

-  
 $R$

2

-  $\cos$   
2

*The values of reference for the tests are estimated using this expression.*

### **3 Modeling**

**With**

#### **3.1**

##### **Characteristics of modeling**

*The concrete veil is represented by elements DKT, supported by meshes quadrangles to 4 nodes: one counts 10 meshes on a vertical generator and 32 on a horizontal half-circle. With this provision, the meshes have dimensions close to those of a square of 1 m on side.*

*A thickness  $E = 0,6 \text{ m}$  is assigned to all the meshes of the veil, as well as a material concrete for which are defined behaviors ELAS and BPEL\_BETON: the parameters take the values data previously in paragraph [§ 2.2.1].*

*Each cable is represented by 128 elements MECA\_BARRE, supported by meshes segments with 2 nodes. On a horizontal half-circle, one thus counts 4 times more meshes on one cable than on the concrete veil.*

*A surface of cross-section  $Its = 1,5.104 \text{ m}^2$  is assigned to all the meshes of the cables, like one material steel for which behaviors ELAS and BPEL\_ACIER are defined: parameters take the values given previously in paragraph [§ 2.2.2].*

*The  $F0$  tension =  $2.105 \text{ NR}$  is applied to the two nodes ends of each cable. The value of this tension is coherent with the values of section and of stress ultimate elastic, for cables of prestressed toronés. The evaluation of the losses of tension by relieving and retreat with anchorings is carried out in accordance with the rules of the BPEL; the parameters take the values given previously in paragraph [§ 2.2.3].*

*As one applies the same tension at the two ends of each cable, and as one imposes the same retreat with anchorings, the profiles of tension obtained must be symmetrical compared to nodes mediums of the cables.*

*Taking into account the geometrical characteristics and grid, nodes of the cables  $n^{\circ}1$  and  $n^{\circ}2$  project on the nodes tops and the edges of the meshes of the concrete veil. For the nodes of these two cables, the indices of projection obtained must be in conformity with the following sequence: 2 for the first node, then 13-13-13-2 until the last node.*

*The nodes of the cables  $n^{\circ}3$  and  $n^{\circ}4$  are projected as for them on the edges and inside the meshes of veil concrete. For the nodes of these two cables, the indices of projection obtained must be in conformity with the following sequence: 14 for the first node, then 0-0-0-12 until the last node.*

*The rule of assignment of the index of projection is previously defined in paragraph [§ 3.3].*

*Taking into account the characteristics of the grid, the eccentricities of the nodes of the cables are evaluated*

*3  
using the expression of the paragraph [§ 3.4] with =  
and  
= 0*

*,  
,*

, .  
32  
4  
2  
4

### **3.2 Functionalities tested**

*The functionalities which one wishes to validate are as follows:*

.  
*operator DEF1\_MATERIAU [U4.23.01]  
: definition of the relations of behavior  
BPEL\_BETON and BPEL\_ACIER, if all possible losses of tension  
are taken into account;*

.  
*operator DEF1\_CABLE\_BP [U4.23.06]: calculation of the profiles of tension along the cables of  
prestressed; projection of the nodes of the cables on the meshes of the concrete veil,  
preliminary with the calculation of the coefficients of the relations kinematics between the DDL of the  
nodes  
cables and DDL of the nodes “close” to the concrete veil.*

## **4.2 Remarks**

**One clearly obtains relative variations for the cumulated angular deviation of an order of magnitude higher than those obtained for the curvilinear X-coordinate, which is calculated with very good precision.**

**The cause is inherent in the method of interpolation spline cubic used to interpolate them trajectories of the cables. This method consists in interpolating the trajectory on each subinterval by a polynomial of order 3, by guaranteeing the continuity of the derived first and the derivative seconds at the boundaries of the subintervals. The interpolation of a circular trajectory by**

*polynomials of order 3 is in is an approximation, of which the effects are more sensitive on the derivative*

*seconds that on the derivative first.*

*This is why precision obtained for the curvilinear X-coordinate, calculated using the derivative first of the trajectory, is definitely better than that obtained for the angular deviation cumulated, calculated using products crossed between the derivative first and the derivative second. To improve the precision on the cumulated angular deviation, it would appreciably be necessary to refine it*

*grid: this step is not valid a priori, because it would lead to overcosts of calculation very consequent for a weak profit of precision.*

*One obtains indeed symmetrical profiles of tension compared to the nodes mediums of the cables. The variations by defect on the curvilinear X-coordinate and the cumulated angular deviation induce variations*

*by excess on the calculated values of tension, but the precision remains satisfactory: this validates method of calculation.*

*The indices of projection obtained are in conformity with those awaited, and the eccentricities are calculated*

*with a very good precision: this validates the operations of projection.*

#### *4.3 Parameters of execution*

*Version: 5.07.01*

*Machine: SGI/ORIGIN 2000 R12000*

*System:*

*Obstruction memory:*

*64 Mo*

*Time CPU To use: 14 seconds*

## *5*

### *Summary of the results*

*The results obtained are validated by comparison with those theoretically awaited with one good precision.*

*The particular functionalities tested are as follows:*

.

*operator DEF1\_MATERIAU [U4.23.01]: definition of the parameters characteristic of materials steel and concrete allowing the calculation of the tension along the cables of prestressed, in accordance with the rules of the BPEL;*

*operator DEF1\_CABLE\_BP [U4.23.06]: calculation of the tension along the cables; projection nodes of the cables on the meshes representing the structure of concrete, preliminary with calculation of the coefficients of the relations kinematics between the DDL of the nodes of the cables and them*  
*DDL of the nodes "close" to the structure of concrete.*

***ZZZZ112 - Roll under variable pressure.  
Validation of LIRE\_PLEXUS***

***Summary:***

***The purpose of this test is to validate the operation of order LIRE\_PLEXUS. This one makes it possible to read fields of pressures calculated by PLEXUS on a telegraphic grid, and to apply these pressures to a grid composed of hulls or telegraphic elements.***

***This test has an analytical solution: it is about a cylinder subjected to a pressure which varies linearly along its axis.***

***Two modelings are proposed: the cylinder is with a grid in elements DKT (modeling A) or in elements COQUE\_3D (modeling B).***

***The results differ from the reference solution only by the lack of refinement of the grid of hulls (in particular for modeling A).***

***This test thus validates order LIRE\_PLEXUS.***

**CYRANO3-Code\_Aster**

**Summary:**

**This test makes it possible to validate nonthe regression of the tool for chaining C3ASTER between codes CYRANO3 and**

**Code\_Aster. Two-dimensional modeling represents the unit pelletizes sheath in a plan (R, Z) and**

*three-dimensional modeling is contingent on a structure made up of two fragments of pastille and an edge of sheath of fuel pin. In three-dimensional modeling, the chaining makes it possible to model one slice fuel pin in the plan (R, théta) with a 0,1 mm thickness in order to simulate the efforts axial. The pellet-sheath spaces inter-fragments and play are modelled by elements 3D of contact-friction.*

*The loadings and the initial conditions come from a base of results CYRANO3. The chaining provides in Code\_Aster of the files of grid and data of orders.*

*The versions considered here are:*

- *CYRANO3, version 2.6,*
- *C3ASTER, version 3.0.*

*The file of validation for this test is to be begun again since values of not-regression changed for modelings has and C since version 5.4.8 compared to the establishment of origin per Mr. Bonnamy in version*

*5.1.8. The values of origin of version 5.1.8 are indicated in reference.*

## **Summary of the results**

Not-regression. The file of validation for this test is to be begun again since values of not-regression changed for modelings has and C since its establishment of origin by Mr. Bonnamy in version 5.4.8. The values of origin of version 5.1.8 are indicated in reference. One can nevertheless suppose that the new values obtained are better insofar as the results on the constraints between modelings has and B or C and B approach. But that remains to check.

***validated***

***Orders***

## **Keys**

**PROJ\_CHAMP VIS\_A\_VIS**

**GROUP\_MA\_1**

**[U4.53.05]**

**METHOD**

**“ELEM”**

*The validation relates to method “ELEM in the case of” the surface meshes plunged in R3 space. One also tests key word VIS\_A\_VIS for method “ELEM”.*

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

*For the field ch1, calculated on the grid ma1, the reference solution is obtained with Code\_Aster (version 5.02.07).*

*For the field ch1bis obtained by a projection “return ticket” (ma1 - > ma2 - > ma1), the solution of reference is the field ch1.*

*One thus measures the error due to 2 successive projections of fields: ch1 - > ch2 - > ch1bis*

***ZZZZ121 - Adaptation of grid with LOBSTER***

***Summary***

***This series of case-tests validates by means of computer the adaptation of grid with LOBSTER. On a grid simple, either in 2D, or in 3D, a static calculation of mechanics is launched, with production of an indicator***

***errors. From there, a call to the software LOBSTER will involve a modification of the grid. On it new grid, a new calculation of static mechanics is activated, corresponding to the same problem physics.***

***These case-tests are not examples of the interest of the adaptation of grid. They are used only as tests of not-regression of the functionality in the various possible configurations.***

**4/20**

### **1 Context**

***The objective is only to test the not-regression of the future evolutions of ASTER and LOBSTER. Even if the case-tests are realistic from the physical point of view for representing studies well real, one should not attach importance to the value of the results.***

***In particular, one should not anything deduce some as for the performance indicating couple from error adaptation of grid.***

***These case-tests validate the operation of two macro orders MACR\_INFO\_MAIL and MACR\_ADAP\_MAIL which control the whole of the process.***

***More precisely, the functionalities tested are as follows:***

•  
*readings and writings of grid and fields to format MED. They are the orders IMPR\_RESU, LIRE\_CHAMP and LIRE\_MAILLAGE with key word MED like format,*

•  
*writing of the data file for LOBSTER: order IMPR\_FICO\_HOMA,*

•  
*launching of the procedure managing the LOBSTER execution. It is the order EXEC\_LOGICIEL; it calls a script with a variable number of arguments,*

•  
*piloting of the whole of the process by the python: macr\_adap\_mail\_ops.py.*

*The process is a priori insensitive with modeling considered. The two important points which cause different treatments in the data exchange between LOBSTER and Code\_Aster are the types of elements and the update of fields on the new grid. We consider thus 4 modelings which are distributed as follows:*

*Modeling*

*Dimension*

*Update of fields*

*With 2D*

*triangles*

*Not*

*B 3D*

*tetrahedrons*

*Not*

*C 2D*

*triangles*

*Yes*

*D 2D*

*quadrangles*

*Not*

*The not-regression is tested on the value of the field of displacement, constraint or temperature in a free node. The test takes place for two resolutions, those with the grids resulting from the first and*

*of another adaptation. Indeed, the data transmissions and LOBSTER piloting are not the same ones for the first adaptation and the following ones. At least two passages thus should be tested.*

### **2.1.3 The two-dimensional case of modeling D**

**This case is a copy of case-test SSLV111.**

**B (0; 4)**

**C (4; 4)**

**= / 3**

**To (0; 1)**

**= / 6**

**D (4; 0)**

**E (1; 0)**

## **2.2**

### **Properties of material**

**Two distinct materials are used. This difference makes it possible to make sure that the under-fields are well reconstituted after the adaptation of the grid.**

#### **Material 1**

**:**

**E: 180.000 Pa**

**= 0,3 IF**

**= 1,5 105 IF**

**= 7.700 kg.m3**

**= 400 W.K1 m1**

#### **Material 2**

:  
**E: 220.000 Pa**

**= 0,33 IF**

**= 1,6 105 IF**

**= 8.300 kg.m3**

**= 600 W.K1 m1**

***In each case of modelings A, B and C, material 1 is affected with half 1 and material 2 is affected with half 2. In the case of modeling D, the field is homogeneous and is made up material 1.***

***Boundary conditions and changes***

***2.3.1 The two-dimensional case of modelings A and C***

***Imposed displacement:***

*The part is blocked in translation and rotation around the origin.*

*Segment ORIGINE\_J: DNOR = 0*

*ORIGIN: DY = 0*

*Mechanical loading:*

*One applies a pressure to the higher edge.*

*Segment J\_OPPOSE: CLOSE = -1000.*

*For a thermomechanical calculation:*

*The temperature is imposed at the origin:*

*ORIGIN: TEMP = 200.*

*Thermal loading:*

*One applies a convectif exchange with outside to the flat rim.*

*Segment I-OPPOSE: COEFF\_H = 500. TEMP\_EXT = 310.*

*A voluminal source is applied:*

*HALF 1: SOUR = 18 000*

*HALF 2: SOUR = 22 000*

### *2.3.2 The three-dimensional case of modeling B*

*Imposed displacement:*

*The part is blocked in translation and rotation around the origin.*

*ORIGIN: DX = DY = DZ = 0*

*I: DY = DZ = 0*

*J: DZ = 0*

*Mechanical loading:*

*Account of gravity is taken.*

*GRAVITY = 9,81 according to OZ*

*One applies a surface force equal to the weight of the cube, opposite higher.*

*FORCE\_FACE = 78.480 according to OZ*

### 2.3.3 The two-dimensional case of modeling D

*To represent symmetries, the part is blocked in translation on the edges of cut:*

*Vertical edge AB:  $DX = 0$*

*Horizontal edge ED:  $DY = 0$*

### **B**

#### **6.1**

##### **Characteristics of modeling**

***Modeling B tests the coupling between LOBSTER and Code\_Aster for a mechanical problem statics in dimension 3. It is checked that the groups of nodes are preserved at identical and that them groups of elements are regenerated.***

#### **6.2**

##### **Characteristics of the grid**

***The cube is cut out in six tetrahedrons of the type TETR10. The technique is as follows. It is initially half-compartment in two prisms by the diagonal plan of equation  $X = y = 1$ . That corresponds to the two halves defined in the problem. Each prism is then divided into three tetrahedrons.***

***The edges of the cube are with a grid in triangle TRIA6.***

## **12 Summary of the results**

***This case-test having for simple objective the control of nonthe regression, no remark is to be made on the value of the results. The reference is that of Code\_Aster calculation at the day of the first restitution and must be found thereafter.***

***By examining the files orders, one will note that the loadings must be done on entities with suitable dimension.***

***.  
a node for a specific loading; for example a displacement imposed on a corner,  
.***

***a segment for a linear loading; for example, a pressure divided into 2D,  
.***

*a triangle for a surface loading; for example, a force in 3D.*

*In addition, it will be noted that these loadings must be expressed on groups of nodes or of meshes and not on the nodes or and the meshes. Indeed after adaptation of the grid, groups are reconstituted. The ordering of loading is thus the same one, whatever the grid.*

*By complying with these two rules on the loadings, the adaptation of grid is possible.*

***OPERATION: "ADZE"***

***Summary:***

***This test validates the operation "ADZE" of the order CREA\_CHAMP which makes it possible to***

*manufacture a field (with nodes or with the elements) by “assembly” of ends of existing fields.*

*The test consists in affecting on geometrical entities (meshs and nodes), quantities (displacements, internal constraints or variables). One then combines with order ASSE\_CHAMP the fields obtained by assignment and one check that the field result contains the good values.*

***Reference solution***

**2.1**

***Method of calculation used for the reference solution***

***That is to say a size G having 3 components X, Y, Z***

***The grid has 3 geometrical entities (meshs or nodes): X1, X2, X3***

*One first of all manufactures 2 fields ch1 and ch2 by assignment of the size G on the entities geometrical X1, X2 and X3.*

*Entity*

*X1 X2 X3*

*Component*

*X Y Z X Y Z X Y Z*

*ch1*

*1. 3. 1. 3. 1. 3.*

*ch2*

*4. 2. 4. 2. 4. 2.*

*One defines then the fields ch3 and ch4 by:*

*ch3 = CREA\_CHAMP*

*(OPERATION: "ADZE"...*

*ADZE: (ALL: "YES"*

*CHAM\_GD: ch1)*

*ADZE: (ENTITY: X2*

*CHAM\_GD: ch2*

*COEF\_R: 2. )*

*ADZE: (ENTITY: X3*

*CHAM\_GD: ch2*

*COEF\_R: 3.*

*OFFICE PLURALITY: "YES"));*

*ch4 = CREA\_CHAMP*

*(OPERATION: "ADZE"...*

*ADZE: (*

*ALL: "YES" CHAM\_GD: ch3 COEF\_R: 2.*

*NOM\_CMP: "X3"*

*NOM\_CMP\_RESU: "X1")*

*);*

*One must then obtain:*

**Entity**

**X1 X2 X3**

**Component**

**X Y Z X Y Z X Y Z**

**ch1**

**1. 3. 1. 3. 1. 3.**

**ch2**

**4. 2. 4. 2. 4. 2.**

**ch3**

**1. 3. 1. 8. 4. 1. 12. 9.**

**ch4**

**6. 8. 18.**

*To test the various cases of figure of order ASSE\_CHAMP, this calculation is made for 5 types fields:*

**With**

**cham\_no**

**displacements**

**B**

**cham\_elem /ELNO**

**constraints**

**C**

**cham\_elem /ELGA**

**constraints**

**D**

**cham\_elem /ELNO**

**internal variables**

**E**

**cham\_elem /ELGA**

**internal variables**

**2.2**

**Results of reference**

*For the 5 preceding cases of figure, one tests the lubricated and underlined values table below:*

**Entity**

**X1 X2 X3**

**Component**

**X Y Z X Y Z X Y Z**

**ch3**

**1. 3. 1.**

**8. 4. 1. 12. 9.**

**2**

**Reference solution**

**2.1**

***Method of calculation used for the reference solution***

***In each case, one carries out a preliminary calculation with key word LIAISON\_DDL to introduce them linear relations between degrees of freedom. This calculation is used as reference to calculation with the key word LIAISON\_MAIL which generates these linear relations.***

***To obtain the desired linear relations with LIAISON\_MAIL, one writes:***

***Cas1:***

***LIAISON\_MAIL: (  
NOEUD\_2: E***

***MAILLE\_1: Q1***

***CENTER:***

***B***

***ANGL\_NAUT:***

***90.***

***TRAN: (  
-5.***

***0.)***

***)***

***What wants to say that one eliminates the 2 ddls from the node E according to the ddls of the E' point obtained when***

***one subjects to E a rotation of 90 degrees around B then a translation of vector (5,0). E' is thus in the middle of CD. The vector displacement of E is identified (after rotation of 90 degrees) with that***

***of E'. The 2 equations are thus obtained:***

$$DX (E) = DY (E') = 0.5 DY (C) + 0.5 DY (D)$$

$$DY (E) = - DX (E') = -0.5 DX (C) - 0.5 DX (D)$$

***Cas2:***

***LIAISON\_MAIL: (  
MAILLE\_2: S1***

***MAILLE\_1: (Q1, Q2)***

***DDL\_2: "DNOR"***

**DDL\_1: "DNOR"**

**CENTER:**

**B**

**ANGL\_NAUT:**

**180.**

**TRAN: (**

**+5.**

**+10.)**

**)**

*What wants to say that one eliminates normal displacement from the nodes B and E (nodes of the S1 segment)*

*according to the ddls of the points B' and E' obtained when one subjects to B and E a rotation of 180 degrees around B then a translation of vector (+5, +10). B' is thus in the middle of CF and E' with medium of cd. The normal displacement of B is identified (after rotation of 180 degrees) with that of B'.*

*One makes in the same way for B'. The 2 equations then are obtained:*

$$DY(E) = -DY(E') = -0.5DY(C) - 0.5DY(D)$$

$$DY(B) = -DY(B') = -0.5DY(C) - 0.5DY(F)$$

**2.2**

**Results of reference**

*One observes displacement DY of the point F:*

$$\text{cas1: } DY(F) = 1.4153582447720D+00$$

$$\text{cas2: } DY(F) = 1.0561898652983D+00$$

*These displacements are obtained with linear relations enter ddls introduced by the key word LIAISON\_DDL.*

**2.3**

**Uncertainties on the solution**

*No uncertainty.*

## 2

### ***Reference solution***

## 2.1

### ***Method of calculation***

*The reference solution comes from an analytical solution:*

$$xx(X, y, Z) = p \text{ (imposed pressure)}$$

$$yy(X, y, Z) = 0$$

$$ux(X, y, Z) = X p/E$$

$$uy(X, y, Z) = (y+1.5) p/E$$

$$xx(X, y, Z) = p/E$$

$$yy(X, y, Z) = p/E$$

*That is to say:*

$$D xx/d p(X, y, Z) = 1$$

$$D yy/d p(X, y, Z) = 0$$

$$D ux/d p(X, y, Z) = x/E$$

$$D uy/d p(X, y, Z) = (y+1.5) /E$$

$$D xx/d p(X, y, Z) = 1/E$$

$$D yy/d p(X, y, Z) = /E$$

## 2.2

### **Sizes and results of reference**

*Displacement following X to the point CENTERS:*

$$ux(6, 0, Z) = 2.5 E-4$$

*Displacement following y to the point CENTERS:*

$$uy(6, 0, Z) = 2.25 E-5$$

*Sensitivity of displacement following X to the pressure p to the point CENTERS:*

$$D ux/d p(6, 0, Z) = 2.5 E-5$$

*Sensitivity of displacement following there to the pressure p to the point CENTERS:*

$$D uy/d p(6, 0, Z) = 2.25 E-6$$

*Deformation according to xx at the point CENTERS:*

$$xx(6, 0, Z) = 5. E-5$$

*Deformation according to yy at the point CENTERS:*

$$yy(6, 0, Z) = 1.5 E-5$$

*Sensitivity of the deformation according to xx to the pressure p to the point CENTERS:*

$$D xx /d p(6, 0, Z) = -5. E-6$$

*Sensitivity of the deformation according to yy to the pressure p to the point CENTERS:*

$$D yy /d p(6, 0, Z) = 1.5 E-6$$

*Constraint according to xx at the point CENTERS:*

$xx(6, 0, Z) = 10.$

*Constraint according to yy at the point CENTERS:*

$yy(6, 0, Z) = 0.$

*Sensitivity of the constraint according to xx to the pressure p to the point CENTERS:*

$D xx /d p(6, 0, Z) = 1.$

*Sensitivity of the constraint according to yy to the pressure p to the point CENTERS:*

$D yy /d p(6, 0, Z) = 0.$

***Document: VI.01.151***

***SENST01 - Sensitivity in thermics, control  
data processing***

## ***Summary***

***This case test validates nonthe regression of the basic commands of calculation of sensitivity in thermics. It is about to make sure that the insertion of the key word SENSITIVITY in the principal orders remains operational.***

***For that, one studies a phenomenon of thermics in a field 2D, only controlled by conditions with the limits of Dirichlet. The solution in field of temperature is analytical. In the same way, the derivation of it field compared to one of the boundary conditions is analytical. The comparison calculation/reference is thus simple to establish.***

***One analyzes orders THER\_LINEAIRE, EXTR\_RESU, CREA\_CHAMP. It is checked that a calculation in CONTINUATION functions.***

***Handbook of Validation  
V1.01 booklet: Tests of validity of orders  
Document: V1.01.152***

***SENST02 - Sensitivities compared to the temperature  
imposed and on normal flow***

***Summary:***

***In this case-test, it is a question of making sure of the validity of the sensitivities compared to the temperature imposed and on normal flow, in isotropic transitory linear thermics (key word SENSITIVITY of THER\_LINEAIRE and of THER\_NON\_LINE). It is based on the grid of case-test SENST01A treating the transitory thermal answer***

***of a plate 2D\_PLAN subjected to various thermal requests.***

***One tests the good adequacy of the sensitivities sought with their approximation by finished differences, in***

***several points of the grid and at the last moment of the transient. Strategy of calculation by finished differences,***

***more expensive, harder to implement and less robust, is not of course to privilege and does not have virtue that as a test...***

***One carries out these calculations of transitory linear thermics:***

- with THER\_LINEAIRE (modeling A with not lumpés isoparametric elements),***
- with THER\_NON\_LINE (modeling B with lumpés isoparametric elements).***

***They make it possible to check the correct operation of these two operators in the presence of the loadings***

***EXCHANGE, TEMP\_IMPO, SOURCE and FLUX-REP, on meshes 2D lumpées or not, in both***

*following configurations:*

- *in standard calculation (via the finished differences and TEST\_FONCTION),*
- *of sensitivity (via the suitable option of the thermal operators and TEST\_RESU).*

*The results of these two configurations agree quasi-parfaitement what, although logic in theory, is reassuring as for the robustness of programming of these two operators. Especially that they treat differently identical problems (resolution of a linear system for A and algorithm of Newton for B) being also based on distinct modelings (resp. PLAN and PLAN\_DIAG).*

## **Reference solution**

**2.1**

### **Method of calculation used for the reference solutions**

**On such a case of figure, it is not possible to exhume an analytical solution! Calculations of sensitivity validated by centered differences are finished (what allows also at the same time to validate standard calculation).**

**This good adequacy of the sensitivities with their approximation by finished differences is tested in several points of the grid (I, J and CENTER), and at every moment of the transient ( $t_0$ , T1 and  $t_2$ ), in structures of control PYTHON of the command file. It is traced in the file message (one tolerate a maximum variation of 107%). In the file result one retained only the part of this test concerning the point CENTERS at the last moment of the transient (the sensitivities via a TEST\_RESU and them**

**differences finished via a TEST\_FONCTION, with a relative tolerance of 106%).**

**In the event of disagreement on results (NOOK), one can thus refine the diagnosis, that is to say in direction of**

**standard problem, either of the derived problem, or of both.**

**Strategy of calculation by differences finished, more expensive, harder to implement and less robust, is not of course to privilege and has virtue only as a test...**

***Summary of the results***

*One checks the excellent adequacy of the calculated sensitivities, via the option SENSITIVITY of THER\_LINEAIRE and of THER\_NON\_LINE, with the values by finished differences (the variation is lower than 10-10%).*

*By crossing the results, it appears that the two thermal operators provide the same ones sensitivities and same finished differences. This variation could besides be tiny room while being more severe on the parameters of convergence of the process of optimization of THER\_NON\_LINE (with with less 3.102% near). What is, in logical theory since the same matrix is assembled and them same second members. And what is also extremely reassuring as for the programming of these assemblies since they are carried out via distinct data-processing routes: one treats differently identical problems (resolution of a linear system for THER\_LINEAIRE and algorithm of Newton for THER\_NON\_LINE) being also based on distinct modelings (resp. PLAN and PLAN\_DIAG).*

*These results make it possible to check the correct operation of the two operators, with EXCHANGE, TEMP\_IMPO, SOURCE and FLUX-REP, on meshes 2D lumpées or not, in both following configurations:*

- in standard calculation (via the finished differences and TEST\_FONCTION),*
- of sensitivity (via the suitable option of the thermal operators and TEST\_RESU).*

**Summary of the results**

**One checks the excellent adequacy of the calculated sensitivities, via the option SENSITIVITY of THER\_LINEAIRE and of THER\_NON\_LINE, with the values by finished differences (the variation is lower than 10-10%).**

*By crossing the results, it appears that the two thermal operators provide the same ones sensitivities and same finished differences. This variation could besides be tiny room while being more severe on the parameters of convergence of the process of optimization of THER\_NON\_LINE (with less 2.103% near). What is, in logical theory since the same matrix is assembled and them same second members. And what is also extremely reassuring as for the programming of these assemblies since they are carried out via distinct data-processing routes: one treats differently identical problems (resolution of a linear system for THER\_LINEAIRE and algorithm of Newton for THER\_NON\_LINE) being also based on distinct modelings (resp. PLAN and PLAN\_DIAG).*

*These results make it possible to check the correct operation of the two operators, with EXCHANGE, TEMP\_IMPO, SOURCE and FLUX-REP, on meshes 2D lumpées or not, in the two configurations following:*

- in standard calculation (via the finished differences and TEST\_FONCTION),*
- of sensitivity (via the suitable option of the thermal operators and TEST\_RESU).*

***SENST04 - Sensitivities compared to the coefficient of exchange-wall and with thermal conductivity***

***Summary:***

***In this analytical case-test, it is a question of making sure of the validity of the sensitivities of the field of temperature and of its flow compared to the coefficient of exchange-wall and conductivity, in isotropic transitory linear thermics***

***(key word SENSITIVITY of THER\_LINEAIRE, THER\_NON\_LINE, CALC\_ELEM and CALC\_NO). It rests on***

*configuration of case-test TTLP100 treating the linear transitory thermal response of two separate plates*

*by a play in which one carries out a transfer of heat.*

*The problem is two-dimensional, but the limiting conditions make that the field of temperature reached*

*quickly the stationary state and depends analytically only on the X-coordinate and the data. One deduces some*

*then easily analytical expressions of the sensitivities of the temperature and its flow compared to thermal parameters which interest us: the coefficient of exchange-wall and conductivity.*

*One thus tests the good adequacy of the sensitivities sought with their analytical values in several points of the grid and at the last moment of the transient. To facilitate later maintenance and by concern of*

*complétude, one also calculates and one tests (via the functionalities PYTHON) the values obtained by differences*

*finished (only in temperature). But this last strategy, more expensive, harder to put in work and less robust, is not of course to privilege and has virtue only as a test...*

*One carries out these calculations of transitory linear thermics:*

- with THER\_LINEAIRE (modeling A),*
- with THER\_NON\_LINE (modeling B).*

*They make it possible to check the correct operation of the two thermal operators and their postprocessings*

*associated loadings ECHANGE\_PAROI and TEMP\_IMPO on isoparametric meshes 2D not lumpées (modeling PLAN), in the two following configurations:*

- in standard calculation (via the finished differences and TEST\_FONCTION),*
- of sensitivity (via the suitable option of the thermal operators and TEST\_RESU).*

*The results of these two configurations agree quasi-parfaitement what, although logic in theory, is reassuring as for the robustness of programming of these two operators. Especially that they treat differently identical problems (resolution of a linear system for A and an algorithm of Newton for B).*

## **4.2**

### **Values tested in flow**

*One tests the validity of the sensitivities of the heat flux calculated via the option SENSITIVITY of CALC\_ELEM and of CALC\_NO (“ANALYTICAL” TEST\_RESU). The relative tolerance, for the component*

*in X, is 1.103% and that absolute, for the component in y, is 1.1011%. One is relatively less severe than previously because of approximation made in CALC\_NO (average arithmetic simple of the fields to the nodes by element).*

## **Summary of the results**

*One checks the good adequacy of the calculated sensitivities (in temperature and flow), via the option SENSITIVITY of THER\_LINEAIRE, THER\_NON\_LINE, CALC\_ELEM and CALC\_NO, with the solutions*

*analytical. In particular, they respect strictly the properties of awaited symmetries.*

*It of in the same way sensitivities exhumed by finished differences (in temperature), which were not added here mainly that to meet later needs for maintenance and by concern of complétude.*

*Moreover the difference between the finished differences and the analytical sensitivities is lower than 105%.*

*By crossing the results, it appears that the two thermal operators provide rigorously same sensitivities (with a margin of at least 108%). What is, in theory, logic since one assembles even matrix and same second members. And what is also extremely reassuring as for programming of these assemblies since they are carried out via data-processing routes often distinct.*

*Linear” and “non-linear” finished differences the “are slightly different (with a margin of 105%!), because*

*the field of temperature results, in the first case, of the resolution of a linear system, in the other case, of a non-linear solvor (phase of prediction + algorithm of Newton). But the difference is anecdotic (and could be reduced besides while being more severe on the parameters of convergence of the process of optimization) and confers the same feeling as for calculations of sensitivity: one is trustful as for the robustness of programming of these two operators, for it type of configuration.*

*These two modelings thus make it possible to check the correct operation of the thermal operators, with ECHANGE\_PAROI and TEMP\_IMPO on not lumpées meshes 2D (ECHANGE\_PAROI is not available in lumpé, although this modeling is rather that recommended in thermics!*

*modeling PLAN), in the two following configurations:*

- in standard calculation (via the finished differences and TEST\_FONCTION),*
- of sensitivity (via the suitable option of the thermal operators and TEST\_RESU).*

*One tests also the correct operation of the operators of postprocessings CALC\_ELEM and CALC\_NO for the calculation of the heat fluxes and their sensitivities.*

dyna\_line\_harm*

*Summary:*

*This case test takes again the geometry and the materials of the case test SDLD21 "System mass-arises to 8 ddl with*

*viscous shock absorber " [V2.01.021]. Calculation carried out is the harmonic response of a dynamic system linear discrete.*

*The functionality tested is the derivation of the fields of displacement, speed and acceleration compared to boundary conditions and with the loadings. These boundary conditions and loadings differ compared to case test SDDL21. Indirectly, functionality of calculation with a real loading in entry of dyna\_line\_harm is tested.*

*The reference calculated using the formal computation software MAPLE is semi-analytical.*

## 2

### *Reference solution*

#### 2.1

##### *Method of calculation*

*This calculation is a validation macro MACR\_RECAL. With this intention, the step is as follows:*

- one chooses a value (known as “value to be identified”) for each parameter and one does it calculation. One thus obtains a history of constraint and cumulated plastic deformation,*
- one supposes now that the values to be identified preceding are unknown for us. Our only information is the history of constraint and cumulated plastic deformation that us will thus considèrerons like an experimental measurement,*
- one then launches optimization to this pseudo experimental measure while taking for each one parameters an arbitrary value,*
- one checks that the values identified by the algorithm are well the values to be identified.*

*This step is very traditional in optimization where it makes it possible to validate the algorithms.*

***Handbook of Validation  
VI.01 booklet: Tests of validity of orders  
Document: VI.01.160***

***SENST05 - Sensitivities compared to heat  
voluminal and with emissivity***

***Summary:***

***In this case-test, it is a question of making sure of the validity of the sensitivities compared to voluminal heat and to the emissivity of a radiation, in isotropic transitory non-linear thermics lumpée (key word SENSITIVITY of THER\_NON\_LINE). It is based on the grid of case-test SENST01A treating the transitory thermal answer of a plate 2D\_PLAN subjected to various thermal requests. One tests the good adequacy of the sensitivities sought with their approximation by finished differences, in several points of the grid and at the last moment of the transient. Strategy of calculation by finished differences, more expensive, harder to implement and less robust, is not of course to privilege and does not have virtue that as a test...***

***One thus checks the correct operation of THER\_NON\_LINE with loadings EXCHANGE, TEMP\_IMPO and RADIATION, on lumpées isoparametric meshes 2D, in the two following configurations:***

- in standard calculation (via the finished differences and TEST\_FONCTION),***
- of sensitivity (via the suitable option of the thermal operator and TEST\_RESU).***

**Reference solution**

**2.1**

**Method of calculation used for the reference solutions**

*On such a case of figure, it is not possible to exhume an analytical solution! Calculations of sensitivity validated by centered differences are finished (what allows also at the same time to validate standard calculation).*

*This good adequacy of the sensitivities with their approximation by finished differences is tested in several points of the grid (I, J and CENTER), and at every moment of the transient (t0, T1 and t2), in structures of control PYTHON of the command file. It is traced in the file message (one tolerate a maximum variation of 107%). In the file result one retained only the part of this test concerning the point CENTERS at the last moment of the transient (the sensitivities via a TEST\_RESU and them*

*differences finished via a TEST\_FONCTION, with a relative tolerance of 106%).*

*In the event of disagreement on results (NOOK), one can thus refine the diagnosis, that is to say in direction of*

*standard problem, either of the derived problem, or of both.*

*Strategy of calculation by differences finished, more expensive, harder to implement and less robust, is not of course to privilege and has virtue only as a test...*

**2.2**

**Result of reference**

*Without object.*

**2.3**

**Uncertainty on the solutions**

*Parameters of shift of the finished difference (1 = 104, 2 = 106) and convergence of the grid.*

**Summary of the results**

***One checks the excellent adequacy of the calculated sensitivities, via the option SENSITIVITY of THER\_NON\_LINE, with the values by finished differences (the variation is lower than 1010%).***

***These results make it possible to check the correct operation of the operator with the loadings EXCHANGE, TEMP\_IMPO and RADIATION, on lumpées isoparametric meshes 2D, in two following configurations:***

- in standard calculation (via the finished differences and TEST\_FONCTION),***
- of sensitivity (via the suitable option of the thermal operator and TEST\_RESU).***

*tested*

**Orders**

*IMPR\_RESU FORMAT*

“MED”

*LIRE\_CHAMP FORMAT*

“MED”

*TYPE\_CHAM*

“CHAM\_NO\_DEPL\_R”

*This case tests the various options of writing to format “MED” via order IMPR\_RESU. For that we calculate various options complementary to the only displacement and we create a field of size are equivalent to the field of displacement to the nodes. The impressions are successively those:*

- the field of displacement to the nodes and the stress field at the points of Gauss, expressed on all the grid. That starts the creation of a profile for displacement because it*

*is not defined everywhere: the three nodes “Me, “and “O” do not comprise a value,  
· the field of size. It uses the same profile as the field of displacement of the result  
standard,  
· components “SIXY” and “SIYY” of the stress field to the nodes by element  
“SIGM\_ELNO\_DEPL”,  
· the indicator of error “ERRE\_ELGA\_NORE” on the meshes of the group “MEDIUM”. That  
start the creation of two profiles because the written values are not it on all them  
meshes. The first profile relates to the 4 triangles out of the 8 of the total; the second relates to the 2  
quadrangles on the 4 of the total.*

*The second reading since format “MED” is that of the field of displacement to the nodes contained in  
field of size.*

## **2**

### **Reference solution**

#### **2.1**

##### **Method of calculation**

*The sensitivities of the fields of displacement, speed and acceleration to the data materials are calculated by finished differences. These calculations by finished differences are carried out inside even case test by Code\_Aster. The diagram of finished differences used is as follows (diagram of order 1 not centered):*

*F (,*  
*X)*  
*y*  
*F (x+,)*  
*y - F (,*  
*X)*  
*y*

*X*

*The field of solution displacement of the standard problem (i.e nonderived) is subjected to a test of non regression. Tests of nonregression are also carried out on the sensitivities.*

## **2.2**

### ***Sizes and results of reference***

*The parameters of sensitivity are the Young modulus E and the Poisson's ratio.*

*By finished differences:*

*derived compared to E from displacement following y to the node OPPOSES to the frequency of 10 Hz,*

*derived compared to displacement following y to the node OPPOSES to the frequency of 10 Hz.*

*By nonregression:*

*displacement following Z of the node OPPOSES to the frequency of 10 Hz,*

*derived compared to E of acceleration following y to the node OPPOSES to the frequency of 40 Hz,*

*derived compared to acceleration according to X with the node OPPOSES to the frequency of 40 Hz.*

## **2.3 Uncertainties**

*Results depending amongst other things on the convergence of calculations (what can disturb the values of reference calculated by difference-finished); uncertainty on the solution can be estimated order from 0.5% for the values tested significant (not too small).*

## **Reference solution**

**2.1**

### **Method of calculation**

*The sensitivities of the fields displacement, speed and acceleration with the data materials are calculated by finished differences. These calculations by finished differences are carried out inside even case test by Code\_Aster. The diagram of finished differences used is as follows (diagram of order 1 not centered):*

$F (,$   
 $X)$   
 $y$   
 $F (x+,)$   
 $y - F (,$   
 $X)$   
 $y$

$X$

*The field of solution displacement of the standard problem (i.e nonderived) is subjected to a test of not regression. Tests of nonregression are also carried out on the sensitivities.*

**2.2**

### **Sizes and results of reference**

*By finished differences:*

*To 10 Hz:*

*derived compared to E from displacements in y to the group from nodes OPPOSES,*  
*derived compared to displacements in y with the group from nodes OPPOSES,*  
*derived compared to 1*

*F of displacements in y to the group of nodes OPPOSES,  
derived compared to 2*

*F of displacements in y to the group of nodes OPPOSES.*

*By nonregression:*

*To 10 Hz:*

*displacements in X with the group of nodes OPPOSES*

*To 25 Hz:*

*derived compared to E from accelerations in y to the group from nodes OPPOSES,*

*derived compared to accelerations in X with the group from nodes OPPOSES,*

*To 40 Hz:*

*derived compared to 1*

*F speeds in X to the group of nodes OPPOSES,*

*derived compared to 2*

*F of displacements in X to the group of nodes OPPOSES.*

***ZZZZ164 - Validation of the key words TRANSLATION, ROTATION, MODI\_BASE and SCALE of order MODI\_MAILLAGE***

***Summary:***

***This test validates the key words TRANSLATION, ROTATION, MODI\_BASE and SCALE of MODI\_MAILLAGE. In this goal, one will impose on two grids, one 3D and the other 2D two combinations of these key words. The first is made up of a translation, two unspecified rotations and a scaling. One thus will test them two possibilities of definition of the axis of rotation: either by two points, or by a point and the direction. second will combine a basic change and a scaling. One will thus have tested all the cases thus of figures authorized by these key words.***

**V1.01.164-A Page:**  
**3/6**

**2**  
**Reference solution**

**2.1**  
**Method of calculation**

*The reference solution is analytical.*

*Either  $M(X, y, Z)$  a point of space, one imposes a translation  $T$  of vector  $(tx, ty, tz)$ , and one to him rotation  $R$  of angle (in radians) whose axis passes by  $P(px, py, pz)$  and has as a direction*

*(  
 $D dx, Dy, dz$ ).*

*Then  $M$  becomes  $MT$  after the translation:  $MT(X + tx, y + ty, Z + tz)$ .*

*$MT$  becomes  $MTR$  after rotation:*

*$M$   
 $= P + \cos PM$*

*$TR$   
 $T + (1 - \cos)(PM$*

*$D$   
 $T$   
 $) D + \sin(D PMT)$*

*With  $M$*

*$= M + T$   
 $T$*

*The scaling of a factor ech, gives:*

*$MTRE = ech MTR$*

*The functionality of basic change awaits in entry the data by the user of two vectors orthogonal in 3D (only one vector in 2D). One comes to supplement these data in order to generate one*

*base orthogonal direct, in 3D or 2D. Tests are carried out in order to check if the data of entry will allow to define a direct orthogonal base. A standardization of the vectors of base is then carried out.*

*In 3D, one thus awaits the data of  $U$  and  $V$ , the first two vectors of the new base:*

*$W(X, y, Z) = U(X, y, Z) V(X, y, Z)$   
 $B = (U, V, W)$*

*formed*

*stamp*

:

*by*

*base*

*of*

*vectors*

*M (U, V, W) BT*

=

*M (X, y, Z)*

*In 2D, one generates the second vector of the base by rotation of 90° of the vector seized by the user. This basic change can be combined with a scaling and a translation, for example. The programming of these transformations is done differently in 3D and 2D, so as to optimize each one of these two cases.*

**2.2**

*Sizes and results of reference*

*One will control the new co-ordinates of the P1 point, P7 and P8 in 3D (P1, P3 and P4 in 2D).*

**2.3**

*Uncertainties on the solution*

*Uncertainties come from the numerical precision in Code\_Aster (dependence of the platform) and in the calculation of the analytical solution of reference. One can thus consider a criterion of precision relative about 1.E-13 in the tests.*

**2.4 References**

*bibliographical*

### **3 Modeling**

**With**

#### **3.1**

##### **Characteristics of modeling**

**One places oneself within a framework massive 3D. One will impose successively:**

- a translation of vector (2,5 3,9 -12,3),**
- a rotation of angle 33 degrees and axis passing by the items (10 0,5.3,8) and (0 10 0),**
- the second rotation of angle -161 degrees and axis passing by (- 3 0,5.3,8) and from direction (0 1 0),**
- a scaling of a factor 5.**

**One thus tests all the cases of figure authorized by the syntax of the key words TRANSLATION, ROTATION and SCALE.**

**Then, one sets out again of the initial grid and one imposes to him successively:**

- a basic change of vectors (1,23 0,23 0) and (- 2.3 12,3 0),**
- a scaling of a factor 5.**

**One tests together thus the key words MODI\_BASE and SCALE.**

## ***ZZZZ166 - Calculation of flow in thermics***

### ***Summary:***

***This test has as an aim the validation of the options of calculation of flow in thermics:  
FLUX\_ELGA\_TEMP and  
FLUX\_ELNO\_TEMP.***

### ***6 modelings tested are:***

- A In PLANE 2D: triangles of degree 1, quadrangles of degree 1 and 2 and quadrangles with 9 nodes,***
- B In 2D PLAN\_DIAG: triangles of degree 1 and 2, quadrangles of degree 1 and quadrangles with 9 nodes,***
- C In 2D AXIS: triangles of degree 1, quadrangles of degree 1 and 2 and quadrangles with 9 nodes,***
- D In 2D AXIS\_DIAG: triangles of degree 1 and 2, quadrangles of degree 1 and quadrangles with 9 nodes,***
- E In 3D: hexahedrons, pentahedrons, pyramids and tetrahedrons of degree 1 and 2, hexahedrons with 27 nodes,***
- F In 3D\_DIAG: hexahedrons, pentahedrons, pyramids and tetrahedrons of degree 1.***

***For all modelings 2D.***

***For modelings 3D.***

*(Note:: in AXIS and AXIS\_DIAG, the axis  
(Note:: in 3D\_DIAG, only them*

*of rotation is OY and X-coordinate X corresponds  
4  
hexahedrons in bottom on the left are*

*thus with the ray).  
with a grid).*

## **1.2 Material properties**

*The thermal properties applied to the model are:  
· = 1.0 W/m °C*

## **1.3 Boundary conditions and loadings**

*Nondefinite.*

## **1.4 Field of temperature**

*The field of temperature is directly affected with the model starting from a function. For each modeling, the calculation of flow is tested for a linear thermal field and a thermal field quadratic.*

*For modelings PLANE 2D and PLAN\_DIAG (modelings A and B), the two fields successively affected are:*

- $T(X, Y) = 2.X + 3.Y$*
- $T(X, Y) = 2.X^2 + 3.Y^2$*

*For modelings 2D AXIS and AXIS\_DIAG (modelings C and D), the two fields successively affected are:*

- $T(X, Y, Z) = 2.R + 3.Y$  (with  $R =$   
2  
2*

*$X + Z = X$  in the plan of grid (OXY))*

- $T(X, Y, Z) = 2.R^2 + 3.Y^2$*

*For modelings 3D and 3D\_DIAG (modelings E and F), the two fields successively affected are:*

- $T(X, Y, Z) = 2.X + 3.Y + 4.Z$*
- $T(X, Y, Z) = 2.X^2 + 3.Y^2 + 4Z^2$*

**Code\_Aster** ®

**Version**

**6.4**

**Titrate:**

**ZZZZ166 - Calculation of flow in thermics**

**Date:**

**03/06/03**

**Author (S):**

**J. PELLETT, Key P. HERMAN**

**:**

**VI.01.166-A Page:**

**3/18**

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**The reference solution is analytical:**

**T**

**X = -.**

**X**

**T**

**y = -.**

**Y**

**T**

**Z = -.**

**(**

**only**

**3D**

*in*

)

**Z**

*Taking into account the value (=1), the flow obtained for each configuration is thus:*

*For modelings PLANE 2D and PLAN\_DIAG (modelings A and B):*

- $T(X, Y) = 2.X + 3.Y$   $X(X, Y) = 2$  and  $y(X, Y) = 3$
- $T(X, Y) = 2.X^2 + 3.Y^2$   $X(X, Y) = 4.X$  and  $y(X, Y) = 6.Y$

*For modelings 2D AXIS and AXIS\_DIAG (modelings C and D):*

- $T(X, Y, Z) = 2.R + 3.Y$  ( $R=X$  in plan (OXY))  $X(X, Y, Z) = 2$  and  $y(X, Y, Z) = 3$
- $T(X, Y, Z) = 2.R^2 + 3.Y^2$  ( $R=X$  in plan (OXY))  $X(X, Y, Z) = 4.X$  and  $y(X, Y, Z) = 6.Y$

*For modelings 3D and 3D\_DIAG (modelings E and F):*

- $T(X, Y, Z) = 2.X + 3.Y + 4.Z$   $X(X, Y, Z) = 2$ ,  $y(X, Y, Z) = 3$  and  $Z(X, Y, Z) = 4$
- $T(X, Y, Z) = 2.X^2 + 3.Y^2 + 4.Z^2$   $X(X, Y, Z) = 4.X$ ,  $y(X, Y, Z) = 6.Y$  and  $Z(X, Y, Z) = 8.Z$

**2.2**

*Results of reference*

*For modelings 2D (PLANE, PLAN\_DIAG, AXIS and AXIS\_DIAG), the values tested are:*

- *With the linear field of temperature: the temperature with the nodes A, C, J and L, flow according to X and Y by element with nodes A, C, J and L and flow at the first point of Gauss of same elements,*
- *With the quadratic field of temperature: the temperature with nodes A, C, J and L, and flow according to X and Y by element with nodes A, C, J and L.*

*For modelings 3D (3D and 3D\_DIAG), the values tested are:*

- *With the linear field of temperature: the temperature with the Di nodes, flow following X and Y by element with the Di nodes and flow at the first point of Gauss of the same elements,*
- *With the quadratic field of temperature: the temperature with the Di nodes, and following flow X and Y by element with the Di nodes.*

*With I = 1 to 9 for modeling 3D and I = 1 to 4 for modeling 3D\_DIAG.*

*With a linear field of temperature (and a constant flow):*

*· All modelings give exact results.*

*With a quadratic field of temperature (and a linear flow):*

*· The results are exact with elements of order 2 and one modeling not DIAG. These elements having quadratic functions of form can represent the field exactly of temperature imposed. Flows are exact and would be it still with a discretization more coarse.*

*· The elements of order 2 with a modeling DIAG are treated like elements of order 1 for the calculation of flow. For these elements, flows are constant by element. The error is thus directly related to the size of the elements.*

## ***SENSD04 - Sensitivity to the loading and C.L in dyna\_line\_tran***

### ***Summary:***

*This case test takes again the geometry and materials of the case test SENSD01 “Sensitivity to the loading and C.L. in dyna\_line\_harm ” [V1.01.158]. Calculation carried out is the transitory response of a linear discrete system not deadened.*

*The functionality tested is the derivation of the fields of displacement, speed and acceleration compared to boundary conditions and with the loadings.*

*The reference was obtained with Code\_Aster version 7.1.3 per direct application of the “derived” loading on standard calculation.*

## **Reference solution**

2.1

### **Method of calculation**

*The equilibrium equation of the standard problem can be written in the following matric form:*

$$\mathbf{M}(p) \dot{\mathbf{X}}(T, p) + \mathbf{C}(p) \mathbf{X}(T, p) + \mathbf{K}(T, p) \mathbf{X}(T, p) = \mathbf{F}(T, p)$$

*where:*

*.*

*$\mathbf{M}$ ,  $\mathbf{C}$  and  $\mathbf{K}$  are respectively the matrices of mass, damping and stiffness of model,*

*.*

*$\mathbf{X}$  indicates the vector made up of  $N$  degrees of freedom of the model,*

*.*

*$\mathbf{F}$  is the vector of the loadings.*

The differential equation governing the derivative compared to the parameters of sensitivity  $p$  of the vector

$\mathbf{X}$

displacement  $\mathbf{X}, \mathbf{Y}$ , are obtained by directly deriving the equilibrium equation compared to

$p$

$p$ . After rearrangement of the terms, one obtains:

$$\begin{aligned}
 & \mathbf{M} ( \\
 & \mathbf{F}, \\
 & \mathbf{M} \\
 & \mathbf{C} \\
 & \mathbf{K} \\
 & p) \mathbf{Y} (T, p) + ( \\
 & \mathbf{C} p) \mathbf{Y} (T, p) + \mathbf{K} (p) \mathbf{Y} (T, p) \\
 & (T p) \\
 & (p) \\
 & = \\
 & - \\
 & \mathbf{X} (T, p) \\
 & (p) \\
 & - \\
 & \mathbf{X} (T, p) \\
 & (p) \\
 & - \\
 & \mathbf{X} (T, p) \\
 & p \\
 & p \\
 & p \\
 & p
 \end{aligned}$$

One can note that the matrices (mass, damping and stiffness) of the system associated with calculation derivative are the same ones as those of the initial problem. Thus, we chose as solution

$\mathbf{F} (T, p)$

of reference, that obtained by direct application of the “derived” loading on the problem

$p$

*standard.*

*In our case, the derivative of the loading compared to 1  
F, respectively 2  
F, corresponds to one  
unit force applied to node 5, respectively applied to node 6. The derivative of the loading  
compared to 1  
D corresponds to a unit displacement applied to node 2.*

## **2.2**

### **Results of reference**

*The parameters of sensitivity considered are: 1*

*F, 2*

*F and 1*

*D.*

*At the moment t<sub>fin</sub>:*

*displacements (X, y, Z) of node 5,*

*derived compared to 1*

*F of displacement and speed of node 5,*

*derived compared to 2*

*F of the displacement and acceleration of node 5,*

*derived compared to 1*

*D of the displacement of node 5.*

## **2.3 Uncertainties**

*The results depend on the temporal discretization and the diagram of integration. Here, we have  
chosen as reference solution that obtained by the implicit scheme of Newmark (with  $\gamma = 0.25$   
and  $\beta = 0.5$ ). We estimate uncertainty on the solution lower than 0.5%.*

## ***Reference solution***

**2.1**

### ***Method of calculation***

*The sensitivities of the fields displacement, speed and acceleration with the data materials are calculated by finished differences. These calculations by finished differences are carried out inside even case test by Code\_Aster. The diagram of finished differences used is as follows (diagram of order 1 not centered):*

$F (,$   
 $X)$   
 $y$   
 $F (x+,)$   
 $y - F (,$   
 $X)$   
 $y$

$X$

*The field of solution displacement of the standard problem (i.e nonderived) is subjected to a test of not regression. Tests of nonregression are also carried out on the sensitivities.*

**2.2**

### ***Sizes and results of reference***

*The parameters of sensitivity are the Young modulus E and the Poisson's ratio.*

*The values of reference are calculated at the moment  $t_{fin}$ .*

*By finished differences:*

*derived compared to E from displacement following y to the node OPPOSES,  
derived compared to displacement following y to the node OPPOSES,*

*By nonregression:*

*displacement following Z of the node OPPOSES  
derived compared to E speed following y to the node OPPOSES,  
derived compared to acceleration according to X with the node OPPOSES,*

## **2.3 Uncertainties**

*The results depend on the temporal discretization and the diagram of integration. Here, we have chosen as reference solution that obtained by the implicit scheme of Newmark (with  $\gamma = 0.25$  and  $\beta = 0.5$ ). We estimate uncertainty on the solution lower than 0.5%.*

## **2**

### **Reference solution**

#### **2.1**

##### **Method of calculation**

*The sensitivities of the fields displacement, speed and acceleration with the data materials are calculated by finished differences. These calculations by finished differences are carried out inside even case test by Code\_Aster. The diagram of finished differences used is as follows (diagram of order 1 not centered):*

*F (,*  
*X)*  
*y*  
*F (x+,)*  
*y - F (,*  
*X)*  
*y*

*X*

*The field of solution displacement of the standard problem (i.e nonderived) is subjected to a test of not regression. Tests of nonregression are also carried out on the sensitivities.*

## **2.2**

### **Sizes and results of reference**

*The values of reference are calculated at the moment  $t_{fin}$ .*

*By finished differences:*

*there derived compared to E of displacements following group from nodes OPPOSES,  
derived compared to E from constraints xx with the group from nodes OPPOSES M14 mesh,  
derived compared to displacements following group from nodes there OPPOSES,  
derived compared to constraints xx with the group from nodes OPPOSES M14 mesh,  
derived compared to 1*

*There F of displacements following group of nodes OPPOSES,  
derived compared to 1*

*F of constraints xx with the group of nodes OPPOSES M14 mesh,  
derived compared to 2*

*There F of displacements following group of nodes OPPOSES,  
derived compared to 2*

*F of constraints xx with the group of nodes OPPOSES M14 mesh.*

*By nonregression:*

*displacements according to X of the group of nodes OPPOSES  
there derived compared to E speeds following group from nodes OPPOSES,  
derived compared to accelerations according to X from the group from nodes OPPOSES,  
derived compared to 1*

*F of displacements according to X of the group of nodes OPPOSES,  
derived compared to 2*

*There F of displacements following group of nodes OPPOSES,  
derived compared to 1*

*F of constraints xx with the group of nodes OPPOSES M14 mesh,  
derived compared to 2*

*F of the constraints yy to the group of nodes OPPOSES M14 mesh.*

## **2.3 Uncertainties**

*The results depend on the temporal discretization and the diagram of integration. Here, we have chosen as reference solution that obtained by the implicit scheme of Newmark (with  $\gamma = 0.25$  and  $\beta = 0.5$ ). We estimate uncertainty on the solution lower than 0.5%.*

## **Reference solution**

**2.1**

### **Method of calculation**

The solution comes from finished differences (approximation of derived with order 1) carried out with *Aster*.

**2.2**

### **Sizes and results of reference**

The position of the mesh 45, noted M45, is as follows (see [§3.1]):

- 5th mesh starting from the segment  $d2$ , while turning towards [ $p$  1,  $I$   $p$  1  $E$ ],
- 3rd mesh starting from section A towards Y positive.

The number of the quoted points is the number of the point of corresponding Gauss of M45.

2 3

***SENSD07 - Sensitivity in nonlinear dynamics  
3D (VON-MISES ISOT)***

***Summary***

***This case test takes again the geometry of test SENSD02 but calculation carried out here is the transitory answer not linear of the system.***

***The functionality tested is the derivation of the fields of displacement and speed compared to the properties materials (Young modulus, Poisson's ratio, slope of the traction diagram, elastic limit), and with loading (nodal force). Two DYNA\_NON\_LINE are connected to also test the functionality of recovery with sensitivity.***

***The reference solution of the sensitivities is calculated by finished differences, then one tests with a loading such as the mode is linear, and one compares with the results of DYNA\_LINE\_TRAN.***

***Problem of reference***

***1.1 Geometry***

***OPPOSE***

***CENTER***

***BORD\_GAU***

***3. m***

***I***

***y***

***10. m***

***1 m < X < 11 m***

***1.5 m < Y < 1.5 m***

***X***

$$0 \text{ m} < Z < 1 \text{ m}$$

Z

## 1.2

### **Properties of material**

$$E = 105 \text{ Pa}$$

$$= 0.3$$

$$AND = 2000 \text{ MPa}$$

$$y = 200 \text{ MPa}$$

$$= 2400 \text{ kg/m}^3$$

The model integrates modal damping ( $\text{amor\_réduit} = 0.07$ ) and damping proportional ( $K + M, = 0. \text{ S and } = 0.3 \text{ s1}$ ).

## 1.3

### **Boundary conditions and loadings**

Boundary conditions:

Line "BORD\_GAU" is blocked according to X, y and Z.

The node "I" is blocked according to X, y and Z.

Loading ( $t_{\text{début}} = 0 \text{ S } T \text{ tfin} = 104 \text{ S}$ ):

On the node "OPPOSES":

nodal force according to X F

-

$$X = F T$$

1

(T T

end

beginning)

1

$$F = 100 * \text{coef\_char},$$

:

nodal force according to y F

-

$$Y = F T$$

2  
(T T  
end  
beginning)  
2  
 $F = 30 * \text{coef\_char}$ ,  
:  
nodal force according to Z F

-  
 $Z = F T$   
  
 $F = 10 * \text{coef\_char}$ .

3  
(T T  
end  
beginning)  
3  
:

With  $\text{coef\_char} = 107$  for the first calculation (into nonlinear) and  $\text{coef\_char} = 1$  for the second calculation (in linear).

### **1.4 Conditions initial**

Initial displacement no one and null initial speed.

## **Reference solution**

2.1

### **Method of calculation**

*The sensitivities of the fields displacement, speed and acceleration with the data materials are calculated by finished differences. These calculations by finished differences are carried out inside even case test by Code\_Aster. The diagram of finished differences used is as follows (diagram of order 1 not centered):*

*F (,  
X)  
y  
F (x+,)  
y - F (,  
X)  
y*

*X*

*The field of solution displacement of the standard problem (i.e nonderived) is subjected to a test of not regression. Tests of nonregression are also carried out on the sensitivities.*

2.2

### **Sizes and results of reference**

*The values of reference are calculated at the moment tfin.*

*By finished differences:*

*derived compared to E speed according to X, y and Z with the node OPPOSES,  
derived compared to speed according to X, y and Z with the node OPPOSES,  
derived compared to AND speed according to X, y and Z with the node OPPOSES,  
derived compared to there speed according to X, y and Z with the node OPPOSES,  
derived compared to I  
F speed according to X, y and Z with the node OPPOSES,*

**Note:**

*In the command file, it is enough to replace `nom_cham=' VITE'` by `nom_cham=' DEPL'` or `nom_cham=' ACCE'` to test (values of reference calculated automatically by finished differences) the derivative compared to these fields.*

*By nonregression:*

*displacement following X of the node OPPOSES  
derived compared to E from displacement according to X to the node OPPOSES,  
derived compared to displacement following y to the node OPPOSES,  
derived compared to AND speed according to Z to the node OPPOSES,  
derived compared to speed according to X to the node OPPOSES there,  
derived compared to AND from acceleration following y to the node OPPOSES,  
derived compared to from acceleration according to Z to the node OPPOSES there,*

*By comparison with DYNA\_LINE\_TRAN:*

*displacement following X of the node OPPOSES  
derived compared to E speed according to X with the node OPPOSES,  
derived compared to speed following y to the node OPPOSES,  
derived compared to l  
F speed following y to the node OPPOSES,  
derived compared to l  
F speed according to Z with the node OPPOSES,*

## **2.3 Uncertainties**

*Results depending amongst other things on the convergence of calculations (what can disturb the values of reference calculated by difference-finished); uncertainty on the solution can be estimated order from 0.5% for the values tested significant (not too small).*

***MODI\_MAILLAGE associated with SYMMETRY and with  
order PROJ\_CHAMP associated with DISTANCE\_MAX***

***Summary:***

***The objective of this case test is to validate order MODI\_MAILLAGE with the key word SYMMETRY  
and  
order PROJ\_CHAMP with key word DISTANCE\_MAX.***

***order MODI\_MAILLAGE, with the key word SYMMETRY makes it possible to take the symmetrical  
one of one  
grid 2D or 3D,***

***order PROJ\_CHAMP with key word DISTANCE\_MAX makes it possible not to project the field on  
the nodes which do not answer the 2 following criteria:  
- the nodes are not in an element of the 1st grid,  
- the nodes are beyond DISTANCE\_MAX.***

***The case test consists in realizing:***

***a thermal study on 1/8ème of structure,***

***the construction of the thermal field on 1/4 of structure by projection of the results obtained on  
1/8ème of structure, with the taking into account of a symmetry plane,***

***a thermal study on 1/4 of structure,***

***the comparison of the field of temperature obtained by projection and a study on 1/4 of structure.***

### **3 Modeling With**

#### **3.1 Characteristics of modeling**

The goal of this modeling is to obtain the solution with the thermal problem starting from calculation carried out on 1/8ème of the structure.

The case test proceeds the following way:

.

reading of the grid, 1/8ème of structure, starting from the file with the format “MED”, order LIRE\_MAILLAGE.

.

reading of the field of temperature starting from the file with format “MED”, order LIRE\_CHAMP.

.

creation of a result starting from the field previously read, order CREA\_RESU.

.

creation of a model starting from the grid previously read, order AFFE\_MODELE.

.

creation of a model for the groups of meshes which belong to the symmetry plane, order AFFE\_MODELE (cf notices n°1).

.

reading of the grid, 1/8ème of structure, starting from the file with the format “MED” and modification of

grid by symmetry compared to the plan (sym) defined by:

$AXE\_1 = (1.0, 1.0, 0.0)$ ,  $AXE\_2 = (0.0, 0.0, -1.0)$ ,  $NOT = (0.0, 0.0, 0.0)$

orders LIRE\_MAILLAGE and MODI\_MAILLAGE.

.

reading of the field of temperature starting from the file with format “MED”, order LIRE\_CHAMP.

.

creation of a result starting from the field previously read, order CREA\_RESU.

.  
creation of a model starting from the symmetrical grid, orders AFFE\_MODELE.

.  
reading of the grid accounting for 1/4 of the structure, orders LIRE\_MAILLAGE.

.  
creation of a model starting from the grid previously read, order AFFE\_MODELE.

.  
projection of the 3 results created starting from the solution calculated on 1/8ème of structure, order PROJ\_CHAMP with key word DISTANCE\_MAX.

.  
extraction of the fields of temperature of the 3 results resulting from projection, orders CREA\_CHAMP.

.  
creation of a null field on the model built on 1/4 of the structure, orders CREA\_CHAMP (cf notices n°2).

.  
combination of all the fields, orders COMB\_CHAM\_NO.

.  
creation of a result starting from the combination of the fields, CREA\_RESU.

### **Notice n°1:**

*In this case test, nodes of the grid, [Figure 3.2-a], belong to the symmetry plane (sym). For these nodes, the projection of the field of temperature will thus be entered 2 times. To avoid once cumulating the field of temperature of too, a solution is to create one model containing only these nodes and to carry out projection on the complete grid. This projected field will be then withdrawn using order COMB\_CHAM\_NO.*

### **Notice n°2:**

*The projection of the fields using order PROJ\_CHAMP and the key word DISTANCE\_MAX makes it possible not to create a field on the nodes which are not contained in one of the elements of the initial grid and which are at a distance higher than DISTANCE\_MAX of the element nearest. When one combines fields using order COMB\_CHAM\_NO, it is the first field with the nodes which is taken as reference. If the field is incomplete, as in our case, the combination does not go to give the anticipated result. The solution is thus to create a null field on all the model and to make use of it like reference field.*

## **3.2**

### **Characteristics of the grid**

The projection of the field of temperature calculated on 1/8ème of structure (grid of [Figure 1.1-a]) is projected on the model built starting from the grid of the 1/4 of structure [Figure 3.2-a)].

### **3.4**

#### **Sizes tested and results**

The test is carried out on the field of temperature.

Result obtained by projection and combination on 1/4 of structure is extracted the field from temperature TEMP1. Result calculated on 1/4 of structure is extracted the 2nd field from temperature TEMP2. These 2 fields are withdrawn using order COMB\_CHAM\_NO, and the test is carried out on the maximum and minimal value of the resulting field. In all points of the structure, one must have TEMP1 = TEMP2, the field resulting from order COMB\_CHAM\_NO must thus be null in all

points.

## 4

### Summary of the results

This case test makes it possible to validate:

.

order MODI\_MAILLAGE associated with the key word SYMMETRY,

order PROJ\_CHAMP associated with key word DISTANCE\_MAX.

The validation is done on all the field of temperature and not only on some points.

When the 2 orders are associated, it should be held account owing to the fact that the fields supported by nodes which belong to the symmetry plane can be entered 2 times.

During the combination of the fields using the order COMB\_CHAM\_NO, it is the structure of first CHAM\_NO which is used as structure of reference. If the structure is incomplete, it is thus necessary to create a CHAM\_NO of reference.

## **2**

### **Reference solution**

#### **2.1**

##### **Method of calculation**

*In the case of a supported supported beam, the Eigen frequency of the mode of inflection number I express yourself in the following way [bib1]:*

*I*

*2*

*I.E.(internal excitation)*

*F =*

*I*

*2L2*

*S*

*With:*

*L: length of the beam*

*E: Young modulus*

*I: quadratic moment of inertia compared to the bending axis*

*: density*

*S: section of the beam*

*The clean deformation of mode I is given by the following relation:*

*ix*

$$y = \sin$$

*I*

*L*

*One can thus obtain in an analytical way the derivative of the Eigen frequency and clean deformation compared to a given parameter.*

## **2.2**

### **Sizes and results of reference**

*The values of reference are obtained analytically.*

*3*

*bh*

*For our case: I =*

*and: S = bh*

*12*

*The derivative of the Eigen frequency compared to the Young modulus E, is thus given by the relation following:*

*F*

*I*

*2*

*H2*

*I =*

*E*

*4L2 12th*

*And the clean deformation does not depend on the Young modulus.*

$$y_i = 0$$
$$E$$

## **2.3 Uncertainties**

*The reference solution is obtained analytically.*

### ***Summary of the results***

*The precision relative of derived from each Eigen frequency compared to the Young modulus is lower than 1% of the theoretical solution. The precision on the derivative of the clean deformation is*

*lower than 10-14 in absolute value.*

*The precision of the results depends obviously on the discretization in finite elements. Here, us modelled the beam in 10 parabolic elements. This discretization is reasonable and precision obtained on the first Eigen frequencies is acceptable.*

*3/4*

*1.4 Problems*

*of orientation*

*It is wanted that the grids of reinforcement are directed circonférentiellement. However, seen the form*

*hemispherical considered, one cannot impose this orientation by AFFE\_CARA\_ELEM in the state current of the code. One thus proposes a Python function allowing it.*

*The principle is as follows:*

*· the axis of the hemisphere is Z*

*· for each mesh, one calculates the vector indicating the ciconférentielle direction by  $V=Z^N$  where NR is the normal with the mesh. One notes  $V= [V_x, V_y, V_z]$  and one defines his projection on plan (XOY)*

*by  $W= [V_x, V_y, 0]$*

*· one calculates the values of ANGL\_REP to be assigned to the current mesh by  $=\arctan (V_y/V_x)$  and*

**=arctan (Vz/norm (W))**

**Function called LIST\_CARA\_CIRCONF buckles on all the meshes roasts, calculates and and creates key words:**

**\_F (SECTION=20.0,  
MAILLE=Nom\_Maille\_Courante,  
EXCENTREMENT=0.0,  
ANGL\_REP= (,)),  
GRILLE\_NCOU=1,  
COEF\_RIGI\_DRZ=1.E-10),**

**and it adds them in a list. One provides then this list to AFFE\_CARA\_ELEM. They are thus obtained orders:**

**LIST\_GRI=LIST\_CARA\_CIRCONF (GROUP\_MA=' GRILLE',  
AXE= (0. , 0. , 1.),  
MODELE=MODEL,

## 2

### **Reference solution**

#### 2.1

##### **Method of calculation**

*At the same time the modes of inflection and the modes of torsion are considered.*

### ***2.1.1 Mode of inflection***

*In the case of a supported supported beam, the Eigen frequency of the mode of inflection number I express yourself in the following way [bib1]:*

$$I \\ 2 \\ I.E.(internal\ excitation) \\ F =$$

$$I \\ 2L2 \\ S$$

*With:  
L: length  
beam*

*of  
E: modulate  
Young  
I  
: moment of*

*quadratiq*

*inertia  
by*

*E*

*with*

*report/ratio*

*inflection*

*of*

*center*

:  
*voluminal*

*mass*  
*S:*  
*beam*

*of*  
*section*

*In the case of a beam with circular section of ray R, one obtains:*

$$I = \frac{2 R E}{F}$$

$$I = 4L^2$$

*The clean deformation of the mode of inflection number I is given by the following relation:*

$$I X = Z = \sin$$

*I*

*L*

### ***2.1.2 Mode of torsion***

*The Eigen frequency of the mode of torsion number I, an embedded fixed beam (in torsion), express yourself in the following way [bib1]:*

$$I = \frac{CG}{F}$$

*I*

$2L$

$I$

$P$

$E$

With:  $G$

: modulate

cisailleme

of

$NT (21+)$

$C$

:

torsion

of

constant

$I$

: moment of

quadratiq

inertia

by

$E$

report/ratio

with

torsion

of

center

$P$

In the case of a beam with circular section of ray  $R$ , one obtains:

$$F = I$$

*E*

*I*

*2L 2 (1+)*

*:*

*VI.01.207-A Page:*

*4/8*

*The clean deformation of the mode of torsion number I is given by the following relation:*

*I X*

*= sin*

*I*

*L*

*One can thus obtain in an analytical way the derivative of the Eigen frequency and clean deformation compared to a given parameter.*

**2.2**

***Sizes and results of reference***

*With the geometrical characteristics and mechanics chosen, the first two modes of the beam are modes of inflection and the third clean mode corresponds to the first mode of torsion.*

*The derivative of the Eigen frequency of inflection are given by the following relations:*

*F*

*F*

*F*

*I*

*I*

=

*and*

*I = 0*

*E*

*2nd*

*The derivative of the Eigen frequency of torsion are given by the following relations:*

## 5

### **Summary of the results**

*Precision relative of derived from each Eigen frequency compared to the Young modulus or to Poisson's ratio is lower than 0.5% of the theoretical solution. Precision on the derivative of clean deformation is lower than 10-10 in absolute value.*

*The precision of the results depends obviously on the discretization in finite elements. Here, us modelled the beam in 10 elements POU\_D\_E. This discretization is reasonable and the precision obtained on the first Eigen frequencies is acceptable.*

### ***Reference solution***

## **2.1**

### ***Method of calculation***

*An isotropic homogeneous plate is considered and one calculates his first clean modes of inflection.*

*In the case of a plate simply pressed on its edges, the Eigen frequency of the mode of inflection number ij is expressed in the following way [bib1]:*

$$f_{ij} = \frac{E}{12(1 - \nu)} \left[ \frac{2a^2 B^2}{I} + \frac{2a^2 B^2}{I} \right]$$

*I: belly of vibration numbers according to dimension has*  
*J: belly of vibration numbers according to the Directorate B*

*E: Young modulus*  
*ν: Poisson's ratio*  
*H: thickness of the plate*  
*ρ: density*

*In the case where, the a/b report/ratio is equal to 2/3, the order of arrangement of the first Eigen frequencies of inflection is as follows: f11, f12, f21, f13, f22, f23,...*

## **2.2 Sizes and results of reference**

*The derivative of the Eigen frequency of inflection are given by the following relations:*

*F*

### **3 Modeling With**

#### **3.1 Characteristics of modeling**

*One considers in this modeling a modal calculation of the plate modelled by elements DKT.  
One calculates then the derivative of the clean modes compared to the Young modulus and compared to  
Poisson's ratio of material constituting the plate.*

#### **3.2 Characteristic of the grid**

*Numbers and type of meshes: 192 elements of the type TRIA3.*

#### **3.3 Functionalities tested**

*The functionalities tested are derivations of real clean modes of plate (DKT) resulting from one  
modal calculation by the method of simultaneous iterations, compared to the Young modulus and the  
coefficient  
of Poisson.*

#### **Orders**

*DEFI\_PARA\_SENSI VALE*

*MODE\_ITER\_SIMULT SENSITIVITY*

*TEST\_RESU SENSITIVITY*

#### **3.4**

## **6 Modeling**

**D**

### **6.1**

#### **Characteristics of modeling**

*One considers a modal calculation of the plate modelled by elements COQUE\_3D. They are calculated derived from the first clean mode compared to the Young modulus and the coefficient from Poisson of material constituting the plate. For this modeling, we introduced one viscous damping proportional in the mechanical characteristics of constituent material the plate ( $AMOR\_ALPHA = 10^{-6} S$ ,  $AMOR\_BETA = 10^{-6} s^{-1}$ ).*

### **6.2**

#### **Characteristic of the grid**

*Numbers and type of meshes: 24 elements of the type QUAD9.*

### **6.3 Functionalities**

#### **tested**

*The functionalities tested are derivations of clean mode complexes hull (COQUE\_3D) resulting from a modal calculation by the method of simultaneous iterations, compared to the Young modulus and with Poisson's ratio.*

#### **Orders**

7

### **Summary of the results**

*The relative precision on the derivative of each Eigen frequency compared to the Young modulus is lower than 2% of the theoretical solution for various modelings of the plate. For derivation compared to the Poisson's ratio, the precision is lower than 4% of the solution theoretical.*

*The precision of the results depends obviously on the discretization in finite elements and on assumptions of plane constraint, small deformation and small displacement.*

*Here, we chose a discretization corresponding to 8 finite elements by wavelength of vibration. This discretization is certainly rather coarse, but it makes it possible nevertheless to obtain one*

*solution acceptable for the derivative of the first three Eigen frequencies of the plate.*

***FETI003 Validation of a calculation FETI with Dirichlet simple***

***Summary:***

***This case-test validates the not-regression of a calculation FETI in linear mechanics: manual partitioning or automatic (MONGREL partitionneurs and SCOTCH TAPE) and calculation multidomaine sequential with Dirichlet simple, homogeneous or not, divided between under-fields or not. It is a question of making sure that insertions of orders DEFI\_PART\_OPS/FETI and of key word SOLVEUR+METHODE=' FETI' in MECA\_STATIQUE remain operational within this framework.***

***One thus checks the validity of automatic partitionings and that of the structures of data FETI and of the algorithmic associated one which manages the conditions of simple Dirichlet.***

***For that one studies a calculation in linear elasticity on a plate 2D not aligned with the principal axes, subjected to a pressure constant and blocked in 3 nodes and on a mesh 1D.***

**N19**

**FETI3**

**N6**

**Appear 3.1-a: Division of square in four under-field**

*Co-ordinates of some points:*

$N1 = \{5.5, 5\}$ ,  $N2 = \{7, 3\}$ ,  $N3 = \{3.5, 3.5\}$ ,  $N4 = \{5, 1.5\}$ ,  $N5 = \{1.5, 2\}$ ,  $N6 = \{3, 0\}$ ,  $N7 = \{0, 4\}$ ,  $N8 = \{2, 5.5\}$ ,  $N9 = \{4, 7\}$ ...

*The interface with direction FETI of the term thus relates to DDLs of the nodes: N1, N3, N4, N5, N8, N16 and*

*N17. These nodes are all multiplicity 2, except N3, of multiplicity 4.*

*The grid is composed of 24 TRIA3 and 4 SEG2 associated with usual modeling 2D\_PLAN with MECHANICAL phenomenon (GROUP\_MA='STRU').*

*The nodes blocked by conditions of simple Dirichlet are: N10, N12 and N13 (DDL\_IMPO). Their LIGREL of load must thus be cut out because it relates to three under-fields. Those blocked by one condition of Dirichlet generalized are: N9 and N11.*

*Calculation FETI is sequential, it is pressed on the preconditionnor lumpé with scaling by nodal multiplicity, a total reorthogonalisation of the directions of descent via a GSM and one seek automatic rigid modes by relative test on the value of the pivots. To obtain one relative residue lower than 10-12, 13 iterations are necessary. The local solvor is the multifrontale with its default settings.*

**YYYY104 - Prismatic test-tube fissured in 3D**

**Summary:**

This case test of elastic design results from an industrial problem. It makes it possible to compare the performances of various solvers established in Code\_Aster, as well as the two methods of treatment of the conditions with limits of the Dirichlet type.

The values of reference result from a calculation carried out on the grid with code PERMAS. The test comprises 11 modelings on the same problem of reference: modeling 3D of a quarter of prismatic test-tube fissured in 4784 pentahedrons with 15 nodes and 598 hexahedrons with 20 nodes, are 16565 nodes.

**In the preceding versions, this case test was named SSLV103.**

Organization (S): EDF/IMA/MMN

**Handbook of Validation**

**V1.10 booklet: Benchmarks**

**V1.10.108 document**

**YYYY108 - Test-tube CTJ25**

**Summary:**

This test has two objectives:

- to ensure itself of nonthe regression of the various methods of resolution of the linear problem of elasticity

with various solveurs or methods of treatments of the boundary conditions kinematics (dualisation or elimination),

- to ensure a follow-up of the performances for a 3D problem of about 10000 ddl.

The test comprises 14 modelings on the same problem of reference: modeling 3D of a quarter of test-tube CTJ25 in 630 hexahedrons for a loading of imposed displacement. Only method of resolution is different with each modeling.

**In the preceding versions this test was named SSLV101.**

**Handbook of Validation**

**V1.10 booklet: Benchmarks**

**Document: V1.10.110**

**YYYY110 - Reactor vessel. Modal analysis**

**Summary:**

This three-dimensional problem consists in seeking modes of vibration of a reactor vessel modelled by elements of hull or beams. This test of mechanics of the structures corresponds to an analysis dynamics of an assembled structure having a linear behavior. It includes/understands two modelings (two solveurs of resolution of system linear are tested).

Via this problem, one tests the element of hull DKT, the element of beam of Timoshenko, it calculation of the clean modes by the method of Lanczos.

There are no results of reference. They were only compared with modelings by “beams equivalent ” and they were in concord.

This test also makes it possible to ensure a follow-up of the performances in particular of order

MODE\_ITER\_SIMULT

and of the methods of resolution of linear systems LDLT and MULT\_FRONT.

### **Problem of reference**

#### **1.1 Geometry**

encass 1

supp\_cuv

**1.2**

#### **Material properties**

For the part modelled by hulls (steel):

$E = 2.1 \cdot 10^{11} \text{ Pa}$

$\nu = 0.3$

$\rho = 7.85 \cdot 10^3 \text{ kg/m}^3$

For the part modelled by beams:

$E = 3.15 \cdot 10^{11} \text{ Pa}$

$\nu = 0.3$

$\rho = 7.85 \cdot 10^3 \text{ kg/m}^3$

**1.3**

#### **Boundary conditions**

The groups of nodes SUPP\_CUV and ENCASS1 are embedded (three displacements and the three rotations are blocked).

### **Summary of the results**

Nothing to announce for the moment.

It is noticed that the change of solvor (passage of method LDLT to the method MULT\_FRONT) made it possible to gain approximately a factor 8 on the resolution of the modal problem.

***Handbook of Validation***  
***VI.10 booklet: Benchmarks***  
***Document: VI.10.119***

***ELSA01 - Nonlinear seismic analysis***  
***of a line of piping***

***Summary:***

***This test validates calculations of pipes right and bent in dynamics of the nonlinear structures (DYNA\_NON\_LINE).***

***A seismic excitation is imposed on the line. This one involves a partial plasticization (1%) elbows only. The values tested are displacements. The values of reference are displacements resulting tests ELSA realized at the ECA.***

***Four modelings are tested: a modeling in elements beams of Timoshenko POU\_D\_T with plasticity total (linear isotropic work hardening), modeling A, a modeling in elements PIPE with 3 nodes with taking into account of local plasticity (linear kinematic work hardening), modeling B, a modeling in elements PIPE with 4 nodes, modeling C and a modeling D made up of elements DKQ in the elbows and of PIPE with 3 nodes in the right parts.***

***Calculations carried out let appear that modeling POU\_D\_T gives correct results for first cycles (0,6 to 21% of variation compared to the values measured in displacements), is far from expensive***

***in computing times but takes on the other hand a long time to implement because of necessary identification of one***

***a significant number of parameters of the total criterion of plasticity. This modeling does not make it possible to reach***

***with the constraints.***

***Modeling PIPE with 3 nodes gives good results (0,75% to 12,67% of variation compared to measured displacements). It is more expensive in computing times than modeling POU\_D\_T (7435 dryness***

***CPU 71 dryness) but much faster to implement against since it has the advantage of not to depend on parameters to identify as a preliminary.***

***The use of the element PIPE to 4 nodes allows a significant profit in terms of a number of elements and thus***

*of ddl. For a computing time divided by 2 compared to modeling B, the results remain excellent (3,1 to 5% of variation on displacements). Analysis of the test by modelings PIPE on a number of cycles more important shows than the behavior of material is represented better by a kinematic work hardening*

*linear that a linear isotropic work hardening.*

*Lastly, calculation by a mixed modeling (DKT/PIPE) is much more expensive in computing times (12874 dryness CPU) for a less precision (0,6% to 21% of variation).*

*Very realistic results obtained by modelings PIPE over the total duration of the test comparatively with modelings POU\_D\_T as their fast time of implementation show, in spite of times of calculation more important, interest of this type of modeling for the nonlinear seismic analysis of pipings.*

#### ***Boundary conditions, loadings and initial conditions***

*Embedding in A and B and blocking of the vertical movements out of C.*

*Pressure interns  $P = 12$  MPa.*

*Loading: seism according to identical direction OX for the 2 points of supports A and B (structure mono-supported). It corresponds to the acceleration measured on the level of the mobile plate (see accélérogramme on the following figure). Computing times over the total duration of the test being very important [bib2], calculation presented was carried out until  $T = 1,1$  S (approximately 2 periods).*

*The structure is initially at rest (null speeds and displacements).*

### **3 Modeling**

**With**

#### **3.1**

#### ***Characteristics of modeling***

*The line is modelled in beams of Timoshenko (POU\_D\_T). They are circular and hollow for pipes and full for the rod. The valve is modelled by a discrete element in translation/rotation (DIS\_TR). The rod is modelled in POU\_D\_T like by a discrete element in translation (DIS\_T) in its top.*

*Inertias of the bent parts are divided by the lawful factors of flexibility [bib4] so to take account of the effects of ovalization. The factors of flexibility are given by:*

16

.5

1

F

=

.

RCCM

P.rmoy

1 +

.  $X$

$E$ .

$K$

with:

4

1

$E$ : thickness

$C$

$moy$

$R$

$R$

and  $X$

$C$

=

6

$moy$ : average radius

$R^2$

$K$

$R_c$ : radius of curvature

$moy$

$E$   $moy$

$P$ : internal pressure

$E$ : Young modulus

Plasticity during the tests having remained localised on the level of the elbows (1% of deformation plastic approximately), one admits that only the elements in the bent parts have a behavior elastoplastic (linear isotropic work hardening) and that the right parts have a behavior rubber band. The parameters of the total criterion of plasticity were identified on the calculation of an elbow in monotonous inflection (while comparing with the results of reference obtained by the elements PIPE), them values selected are:

·  
 $y = Z = 0,84$

·  
 $y = Z = 4,0 \cdot 10^{-3}$

·  
*Limiting normal effort:  $N_p = 9,081 \cdot 10^5 \text{ NR}$*

·  
*Moment of the first plasticization of the elbows:  $M_e = 8,48 \cdot 10^3 \text{ N.m}$*

·  
*Plastic bending moment limits elbows:  $M_p = 25 \cdot 10^3 \text{ N.m}$*

·  
*Limiting torque:  $M_{px} = 7,067 \cdot 10^4 \text{ N.m}$*

·  
*One calculates the seismic response until  $T = 1,1 \text{ S}$  with a step of calculation of  $10^{-2}$  seconds. The diagram*

*of integration in time used is that of NEWMARK ( $\alpha = 0,25$   $\delta = 0,5$ ). The problem incremental nonlinear is solved by the method of NEWTON for which the matrix used in the total iterations is the elastic matrix at the time of the phase of the prediction then the matrix tangent reactualized with each iteration for the following iterations.*

**5.1**

## **Characteristics of modeling**

*The line is modelled in elements PIPE in the right parts and the bent parts of piping. The rod is on the other hand always modelled in beams and the valve by a discrete element in translation/rotation.*

*The element PIPE used is the element with 3 nodes comprising 2 layers and 16 sectors. Three modes of Fourier allow to describe ovalization, the swelling and the warping of the sections.*

*As previously, it is admitted that only the elements in the bent parts have one elastoplastic behavior (kinematic work hardening) and that the right parts have one elastic behavior.*

*One uses a step of times of 102 S for temporal integration. The seismic answer is calculated until  $T = 1,1$  S. the diagram of integration in time used is that of NEWMARK ( $\alpha = 0,25$   $\delta = 0,5$ ). The nonlinear incremental problem is solved by the method of NEWTON for which stamp used in the total iterations is the elastic matrix at the time of the phase of the prediction then the tangent matrix reactualized with each iteration for the following iterations.*

## **5.2**

### **Characteristics of the grid**

*Grid of an elbow: 30 elements PIPE with 3 nodes*

*Ddl numbers: 14827*

*A number of nodes: 673*

*A number of meshes and types: 211 SEG3 (left right and bent piping) for the elements PIPE*

*9 SEG2 (3 for the valve and 6 for the rod) for elements POU\_D\_T*

*2 POII (1 for the valve and 1 for the top of the rod)*

*A sight of the grid is given on the following figure.*

## **7 Modeling**

### **C**

#### **7.1**

##### ***Characteristics of modeling***

*The line is modelled in elements PIPE with 4 nodes in the right parts and the bent parts piping. The rod is on the other hand always modelled in beams and the valve by an element discrete in translation/rotation.*

*The element PIPE used is the element comprising 2 layers and 16 sectors. Three modes of Fourier allow to describe ovalization, the swelling and the warping of the sections.*

*As previously, it is admitted that only the elements in the bent parts have one elastoplastic behavior (kinematic work hardening) and that the right parts have one elastic behavior.*

*One uses a step of times of 102 S for temporal integration. The seismic answer is calculated until  $T = 1,1$  S. the diagram of integration in time used is that of NEWMARK ( $\alpha = 0,25$   $\delta = 0,5$ ). The nonlinear incremental problem is solved by the method of NEWTON for which stamp used in the total iterations is the elastic matrix at the time of the phase of the prediction then the tangent matrix reactualized with each iteration for the following iterations.*

#### **7.2**

##### ***Characteristics of the grid***

*Grid of an elbow: 5 elements PIPE with 4 nodes*

*Ddl numbers: 5026*

*A number of nodes: 161*

*A number of meshes and types: 75 SEG4 (left right and bent piping) for the elements PIPE*

*9 SEG2 (3 for the valve and 6 for the rod) for elements POU\_D\_T*

*2 POII (1 for the valve and 1 for the top of the rod)*

*A sight of the grid is given on the following figure.*

## ***9 Modeling***

### ***D***

#### ***9.1***

##### ***Characteristics of modeling***

*The line is modelled in elements PIPE with 3 nodes in the right parts and in elements DKQ in the bent parts of piping. The elements pipes make it possible not to model them right parts contiguous to the elbows in elements DKQ. The rod is on the other hand always modelled in beams and the valve by a discrete element in translation/rotation.*

*The element PIPE used is the element comprising 2 layers and 16 sectors. Three modes of Fourier allow to describe ovalization, the swelling and the warping of the sections.*

*As previously, it is admitted that only the elements in the bent parts have one elastoplastic behavior (kinematic work hardening) and that the right parts have one elastic behavior.*

*The pressure applied in the elbows is modified to hold account owing to the fact that in the hulls pressure is applied to the average surface of the element in not in skin interns ( $P=110,2$  bars with place of 120 bars).*

*One uses a step of times of 102 S for temporal integration. The seismic answer is calculated until  $T = 1,1$  S. the diagram of integration in time used is that of NEWMARK ( $\alpha = 0,25$   $\delta = 0,5$ ). The nonlinear incremental problem is solved by the method of NEWTON for which stamp used in the total iterations is the elastic matrix at the time of the phase of the prediction then the tangent matrix reactualized with each iteration for the following iterations.*

**11 Summary of the results**

**Modeling A, starting from POU\_D\_T, gives correct results (0,6 to 21% of variation by report/ratio with the measured values) and is far from expensive in computing times (71 dryness CPU). It requires, by against, a rather important time of modeling since the criterion of total plasticity depends on one certain number of parameters (coefficients numerical of the criterion of plasticity, limiting moments, factors of flexibility) which must be identified. Moreover, calculation over one longer duration shows that the linear isotropic work hardening of the beams is not representative of the behavior of material under seismic loading (the use of a kinematic work hardening in total plasticity redéveloppeur a new element beam would require). Lastly, one cannot reach the fields of constraints.**

**Modeling B, containing elements PIPE with 3 nodes with linear kinematic work hardening, give good results (0,75% to 12,7% of variation compared to measured displacements). Because of numbers more important of degrees of freedom (14827 ddl against 2512 for modeling A), it is more expensive in computing times than modeling POU\_D\_T (7435 dryness CPU against 71 dryness). However, its implementation is much faster to since it has the advantage of not to depend on parameters to identify as a preliminary.**

**The use of the element PIPE to 4 nodes in modeling C allows a significant profit in terms of a number of elements and thus of ddl (5026 ddl). For a computing time divided by 2 by report/ratio with modeling B, the results are excellent (0,4 to 6,4% of variation). Analysis of the test by**

*modelings PIPE on a more significant number of cycles shows than the behavior of material is represented better by a linear kinematic work hardening than an isotropic work hardening linear.*

*Modeling D, made up of elements DKT in the elbows and PIPE with 3 nodes in right parts is much more expensive in computing times than preceding modelings (12314 dryness CPU). It gives results correct but all the same less precise than the 3 others modelings (0,6% to 21% of variation compared to measured displacements).*

*Very realistic results obtained by modelings PIPE over the total duration of the test compared to modelings POU\_D\_T like their fast time of implementation show, in spite of the times computings more important, interest of this type of modeling for nonlinear seismic analysis of pipings.*

*Document: V2.01.002*

*SDL02 - System mass-arises with 8 degrees of freedom*

*Summary:*

*This two-dimensional problem consists in seeking the frequencies and the modes of vibration of a structure*

*mechanics made up of masses and springs. This case-test of Mechanics of the Structures corresponds to one*

*analyze dynamic of a discrete model having a linear behavior.*

*This test allows a complete validation of the options of modeling of discrete rigidity and mass (without*

*finite elements) offered by order AFFE\_CARA\_ELEM [U4.24.01]. Four different modelings are proposed: two modelings for the discrete elements in translation and two others for the elements discrete in translation/rotation. In addition, various functionalities of orders MODE\_ITER\_INV [U4.52.01] (calculation of values and clean vectors per iteration reverses), MODE\_ITER\_SIMULT [U4.52.02]*

*(calculation of the values and vectors clean by the method of Lanczos) and NORME\_MODE [U4.64.02] (definition of normalizes of a clean vector) are tested.*

*This test refers to a test VPCS, but it was modified. Indeed, the Code\_Aster test directs the system mechanics on an axis  $3y = 4x$ , which makes it possible to validate the entry of the data in local reference mark.*

***SDLD04 - Transitory response of a system***  
***mass-springs subjected to an acceleration***  
***imposed***

***Summary***

***This test consists in calculating the not deadened transitory response of a linear system mass-springs embedded free subjected to an imposed acceleration.***

***One tests the discrete element in traction and compression, the calculation of the clean modes, the static modes and it calculation of the transitory response of a system subjected to an imposed acceleration. Direct calculation is compared response to its calculation by modal recombination.***

***This case test is from guide VPCS. The reference solution is an analytical calculation. Errors on results obtained are normal taking into account the step of time chosen for numerical integration.***

**Author (S):**

**Fe WAECKEL, L. VIVAN Key**

**:**

**V2.01.004-C Page:**

**3/8**

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**One initially calculates the Eigen frequencies  $f_i$  and the clean vectors  $Nor$  associated standardized compared to the matrix of mass. One calculates then the generalized response of the system mono-excited by solving analytically the integral of Duhamel [bib1]. Lastly, one restores on the basis physique displacement relating to point D.**

**Calculation of the Eigen frequencies**

**The matrices of mass and stiffness are as follows:**

$$m \ 0 \ 0$$
$$2 \ - \ 1$$
$$0$$

$$M = 0 \ m \ 0, \ K$$

$$= K - 1$$
$$2 \ -$$

$$1$$

$$0 \ 0$$

$$m$$
$$0 \ -$$

$$1$$

$$1$$

*The Eigen frequencies are solution of the equation*

$$[$$
$$\det K - 2M] = 0, \text{ is}$$

$$3$$

$$K$$

$$- 2$$

$$5$$

$$+$$

$$6 - 1 = 0 \text{ where } = \text{ and } =$$

$$\cdot$$

$$m$$

$$0$$

*Calculation of the generalized response of the mono-excited system*

$$(T) = a.t^2 \text{ with } A = 2.105.$$

*In the absolute reference mark, the fundamental equation of the dynamics of the system mass-springs not deadened is written:  $M\ddot{X} + KX = 0$  have.*

*Absolute displacement  $X_a$  breaks up into a uniform displacement of drive in translation  $X$  and in a relative displacement  $X$*

*E*

*R:  $X$*

*X*

*X*

*has =*

*+*

*R*

*E.*

*The equation of the movement in the relative reference mark is written then:  $M\ddot{X} + KX = -MR\ddot{X}$*

*$M\ddot{X} + KX = -MR\ddot{X}$*

*R*

*R*

*$\ddot{X} = Q$*

*S*

*1*

*1*

*2*

*with  $\ddot{X}$*

*(T) A.*

*S =*

*= T 2 and =*

*1 and thus  $Q = a.t m$*

*1.*

*1*

*1*

*The equation of the movement projected on the basis of dynamic mode standardized compared to stamp of mass is written:*

*T*

### **3 Modeling**

**With**

#### **3.1**

#### **Characteristics of modeling**

**The springs and specific masses are modelled by discrete elements with 3 degrees of freedom “DIS\_T”:**

**Y**

**K**

**K**

**K**

**1**

**2**

**3**

**X**

**NO1**

**NO2**

**NO3**

**NO4**

**Node NO1 is embedded and subjected to an imposed acceleration (T). Displacement is calculated relative of node NO4.**

#### **Calculations by modal synthesis**

**One considers the complete base of the clean modes. Temporal integration is carried out with algorithms of Newmark, Euler and Devogelaere with a step of times of 0,001 S. calculations all the steps of time are filed.**

**One considers a damping reduces no one for the whole of the calculated modes.**

**I**

**The loading is taken into account in the form of vector projected on the modal basis**

**EXCIT: (VECT\_GENE) or in the form of modal component EXCIT: (NUME\_MODE) or both with the time.**

### ***Direct calculations***

***Temporal integration is carried out either with the algorithm of Newmark or with the explicit algorithm***

***differences centered with a step in times of 0,001 S. calculations are filed all the ten steps time.***

#### ***Note:***

***As the diagram of the centered differences can be used only with one matrix of mass diagonal, one calculates the elementary matrices with option MASS\_MECA\_DIAG in the operator CALC\_MATR\_ELEM.***

#### ***Taking into account of an initial state***

***In the two types of calculation, one checks that the relative displacement obtained of a calculation carried out in one***

***time is identical to that obtained in several times, i.e. while regarding as initial state, it result of the last step of calculated time:***

***ETAT\_INIT: (RESU\_GENE: ...) for a calculation by modal synthesis;***

***ETAT\_INIT: (DYNA\_TRAN) or***

***ETAT\_INIT: (DEPL\_INIT: ...***

***VITE\_INIT: .) for a direct calculation.***

#### ***Taking into account of the modes neglected by static correction:***

***One considers a modal base made up of the first two clean modes and one has supplements it by a mode corresponding to the static response of the system studied to a unit loading of type force imposed in the direction X (key words MODE\_CORR and CORR\_STAT in L`operator DYNA\_TRAN\_MODAL).***

## **3.2**

with viscous shock absorber*

**Summary:**

*This one-way problem consists in carrying out a harmonic analysis of a mechanical structure composed of a whole of mass-springs with shock absorbers viscous and subjected to an excitation sinusoidal. This test of mechanics of the structures corresponds to a dynamic analysis of a discrete model having a linear behavior. It includes/understands three modelings.*

*Via this problem, one tests the discrete elements in translation (mass, arises, shock absorber), the definition of a force of specific excitation harmonic, the operator of calculation modal (MODE\_ITER\_SIMULT [U4.52.03]) into quadratic and the operator of harmonic calculation of answer (DYNA\_LINE\_HARM [U4.54.02]).*

*In addition, several operators of postprocessing are tested: RECU\_FONCTION [U4.62.03], TEST\_FONCTION [U4.72.02], RECU\_CHAMP [U4.62.01].*

*Results obtained (field of displacement, speed and acceleration for various frequencies of excitation) are in concord with the results of guide VPCS.*

## 2

### Reference solution

#### 2.1

#### Method of calculation used for the reference solution

The system of differential equations of the second order coupled is form:

$$M \dot{u} + C \dot{u} + K U = F$$

2 - 1

10

- 1 2

- 1

10

-

with  $M$

10

.

.

- 1

- 1 2

2 - 1

- 1 2

- 1

5

-

+

1

2

.

$K = 10$

.

.

.

.

.

- 1

- 1 2

The solution with a harmonic excitation  $\mathbf{F} = \mathbf{F}_0 e^{j\omega t}$

(

) is form  $U = u_0 e^{j\omega t}$ , it

who leads to:  $\mathbf{K} - \mathbf{M}\omega^2 + j\mathbf{C}\omega$

(

)  $u_0 = \mathbf{F}_0$

This system can be solved for all, either directly, or by using the modal transformation with to leave the real clean modes obtained by the conservative system associated  $\mathbf{K} - \mathbf{m}\omega^2$

(

) = 0.

It admits N solutions clean (8 in this case) associated  $2i$  and vectors  $I$  gathered in

2

spectral matrix =

[ ]

[ ]

$I$  and the modal matrix =  $I$ .

The modal transformation consists in writing:  $\mathbf{u}_0 = \mathbf{Q}$  what leads to:

$$[-2 \mathbf{I} + \mathbf{J}] \mathbf{Q} = \mathbf{T} \mathbf{F}_0$$

$\mathbf{I}$  is the identity,

here is diagonal =

[ ]

(

)

$\mathbf{H}$  bus damping is proportional  $\mathbf{C} = \mathbf{K}$ .

$N$

$T$

The answer is written:  $U$

$I$

$I$

0 =

$F$

2

0

$$i=1 \mathbf{I} - 2 + \mathbf{J} \mathbf{H}$$

One obtains the exact solution by taking all the clean modes.

One deduces some:  $\mathbf{u} = \mathbf{J} U$

and

$\mathbf{u}$

2

= -  $U$

0

0

0

0

## 2.2

### Results of reference

Displacement according to X of the P4 point for certain frequencies.

## 2.3

### Uncertainty on the solution

Semi-analytical solution.

## 6 Summary of the results

The results obtained are excellent, which is normal for a direct integration.

***Handbook of Validation***

***V2.01 booklet: Linear dynamics of the discrete systems***

***Document: V2.01.022***

***SDLD22 - Transient of a system mass-arises  
to 8 ddl with viscous shock absorber***

***Summary:***

***The mechanical structure considered is made up of a linear one-way whole of mass-springs with shock absorbers viscous and subjected to a transitory excitation of crenel type.***

***Two modelings are developed. The first retains only the degree of freedom in axial translation of masses, the second considers the axial translation and rotation.***

***This problem makes it possible to test:***

***.  
discrete elements (masses, springs, shock absorbers) in translation-rotation,***

***.  
the definition of a force of specific excitation transitory,***

***.  
the operator of transitory calculation of response by modal recombination (DYNA\_TRAN\_MODAL***

*[U4.53.21]), as well as the recovery with initial conditions (modeling A),*

*the operator of calculation of direct transitory response with the diagram to step of adaptive time (DYNA\_LINE\_TRAN [U4.53.02]) (modeling B).*

*In addition, several operators of postprocessing are tested: RECU\_FONCTION [U4.32.03], TEST\_FONCTION [U4.92.02], RECU\_CHAMP [U4.71.01].*

*The results obtained (field of displacements, speeds) are in concord with the results of the guide VPCS, taken for reference solution.*

**SDL23 - System of masses and springs  
under random excitation**

**Summary:**

***This test is in the course of validation within the framework of the VPCS.***

***It comprises a whole of eight specific masses and nine springs excited by an imposed random force on one of the masses.***

***The excitation is of white vibration type. It is given by the spectral concentration of power of the exciting force.***

***The movement of the excited mass is calculated by a stochastic approach according to different frequential discretizations for the answer.***

***One also calculates in postprocessing the spectral moments of the answer.***

### **3 Modeling**

#### **With**

#### **3.1**

#### **Characteristics of modeling**

#### **Discrete element in translation of the type DIS\_T**

Modeling respects the geometry.

Characteristics of the elements:

With the P1 nodes in P8: matrices of masses of the type M\_T\_D\_N with  $m = 10$  kg.

Elements of spring: a matrix of stiffness of the type K\_T\_D\_L with  $K_x = 105$  N/m

Elements of damping: a matrix of damping of the type A\_T\_D\_L with  $c_x = 50$  N/m

Boundary conditions:

All the DDL are blocked except the DDL dx.

Modal damping is calculated by the operator of modal calculation, it is reinjected like modal damping in random dynamic calculation.

#### **3.2**

#### **Characteristics of the grid**

A number of nodes: 10

A number of meshes and types: 9 SEG2, 10 POI1

## 5 Summary of the results

The preceding tables highlight the importance of the smoothness of the discretization frequential of the DSP response for the calculation of the spectral moments.

The user can choose the step: the frequency band is then discretized in a uniform way and it or the peaks can be badly represented: it is the case with 40 steps of 0.25 Hz, which involves an error

of more than 40% at the spectral time.

More one refines the discretization, better is the result.

To avoid refining unnecessarily far from the peaks, one proposes a discretization by rather broad defect supplemented by a refinement of 50 points of discretization around each peak.

In the case of this test which includes/understands one peak, this discretization by defect makes it possible to estimate spectral moments with a precision of about 2%.

**SDL25 - System mass-arises with shock absorber**

**viscous proportional (spectral answer)**

**Summary**

This one-way problem consists in carrying out a spectral seismic analysis of a mechanical structure composed of a whole of mass-springs with viscous shock absorbers subjected to a seismic request provided in the shape of a spectrum of response of pseudo oscillators in acceleration.

Via this problem, one tests modal combination SRSS of operator COMB\_SISM\_MODAL [U4.54.04]. In addition, several operators of preprocessing are tested; DEFI\_FONCTION and DEFI\_NAPPE.

The results obtained are in concord with the results of guide VPCS.

This test is also a test of resorption of LICE. There are no differences between the ASTER results and them

LICE results.

***Summary:***

***This two-dimensional problem consists in seeking the frequencies, the modes of vibration and them  
depreciation of a mechanical structure made up of masses, springs and shock absorbers viscous. It***

*case-test of Mechanics of the Structures corresponds to a dynamic analysis of a discrete model having one linear behavior.*

*This test allows a complete validation of the options of discrete modeling of rigidity, of damping viscous and of mass (without finite elements) offered by order AFFE\_CARA\_ELEM [U4.42.01]. Five different modelings are proposed: the modeling of the discrete elements is either in translation, or in translation/rotation and is written either in total reference mark, or in local reference mark. In addition, different functionalities of orders MODE\_ITER\_INV [U4.52.04] (search for eigenvalues per iteration opposite), MODE\_ITER\_SIMULT [U4.52.03] (search for eigenvalues by the method of Lanczos) and NORME\_MODE [U4.52.11] (definition of the standard of a clean vector) are tested for this problem quadratic.*

*This test refers to a test VPCS, but it was modified. Indeed, the Aster test directs the mechanical system on an axis  $3y = 4x$ , which makes it possible to validate the entry of the data in local reference mark. The results obtained are in concord with the results of reference.*

**Reference solution**

2.1

**Method of calculation used for the reference solution**

*The reference solution is that given in card SDLD27 of guide VPCS.*

*The problem led to seek the eigenvalues and clean vectors of the dissipative system according to:*

$$\mathbf{M}\dot{\mathbf{u}} + \mathbf{C} \dot{\mathbf{u}} + \mathbf{K}\mathbf{u} = 0$$

*with  $\mathbf{M}$  stamps of mass,  $\mathbf{C}$  stamps damping,  $\mathbf{K}$  stamps rigidity.*

*One associates this dissipative problem, the conservative problem:  $\mathbf{K}\mathbf{u} + \mathbf{M}\dot{\mathbf{u}} = 0$ . In form harmonic, it is written  $\mathbf{K} - 2\mathbf{M} = 0$ .*

*Are  $\lambda = [2v]$  the spectral diagonal matrix of the eigenvalues of this conservative system and  $\mathbf{u} = [\mathbf{v}]$  the corresponding matrix of the clean vectors.*

$T$  $T$ 

$v$  are standardized such as:

$$M = Id$$

$$K = .$$

The solutions of the dissipative system are form:

$$U U \text{ is}$$

$$=$$

$$2$$

$$O$$

from where  $(ms + Cs + K)uo = 0$ .

One breaks up  $uo$  in the base of the  $v$ . There is then  $U$

$$Q$$

$O =$ , from where:

$$(Is^2 + s+) Q = 0 \text{ with } = T$$

$C$  (full matrix)

This problem with the eigenvalues is solved by a method of power reverses while taking for initial estimate  $S = J$

$$v$$

$$v.$$

**and viscous damping nonproportional**  
**Summary:**  
**This problem corresponds to a transitory analysis by modal recombination of a linear discrete system constituted of 8 degrees of freedom. This system has a non-proportional damping. A force transient of the crenel type is applied into 1 degree of freedom.**  
**In this problem the elements DISCRETE with modal masses are tested (M\_T\_D\_N), matrices of**

**rigidity**  
**( $K_T D_L$ ) and matrices of damping ( $A_T D_L$ ) in a modeling.**  
**The problem has a reference solution suggested by commission VPCS. Variations with Code\_Aster do not exceed 1,8%.**

## **Reference solution**

### **2.1**

#### **Method of calculation used for the reference solution**

Numerical integration (approximate) by the direct method using a diagram of integration

numerical by finished differences, the step of time used must be sufficiently small to obtain one

sufficiently precise solution. With one of the diagrams used (method - Newmark improved), the step appointed time was of 0.001s.

Method of - Newmark improved (NEWMARK NR. Mr., "A method of computation for structural

dynamics " proceeding ASCE J. Eng. Mech. Div E-3, July 1959, pp 67-94) use the diagram of integration according to:

**Summary of the results**

*One obtains a relatively good agreement between the calculated solution and solution VPCS (<0.7%) except with moment 0.91 (2.4%). The differences are primarily due to the fact that the moments of test are not given that with 2 significant figures, which does not make it possible to seize the moment sufficiently well of the extremum.*

***V2.01 booklet: Linear dynamics of the discrete systems***

***V2.01.030 document***

***SDLD30 - Spectral seismic response of one system 2 masses and 3 springs multimedia***

***Summary:***

***The problem consists in calculating the spectral response of a system 2 masses - 3 springs subjected to one multiple seismic excitation.***

***One tests the discrete element in traction, the calculation of the clean modes, the static modes and the answer spectral by modal superposition via operator COMB\_SISM\_MODAL. Various office pluralities are tested at the time of calculation of the answers of supports.***

***The results obtained are in very good agreement with the analytical results of reference.***

## ***Reference solution***

2.1

### ***Method of calculation used for the reference solution***

***One calculates the spectral response by modal superposition of a system masses spring subjected to two distinct excitations. One determines the displacement of the masses and the reactions of support to the nodes NO1 and NO4 following axis X.***

***One calculates analytically:***

·  
***Eigen frequencies  $f_i$ ,***

·  
***associated clean vectors  $N_{or}$  standardized compared to the modal mass,***

·  
***static modes of supports  $J$  of the system,***

·  
***factors of modal participation  $P_{ij}$  relating to the supports,***

·  
 ***$R_{mij}$  the maximum of the response of each mode starting from the spectra of excitation,***

·  
 ***$R_{ej}$  the contribution of the movement of drive of each support starting from displacements differentials,***

·  
 ***$R_{cj}$  the static term of correction,***

·  
***primary and secondary components of the response according to the règles of office plurality adopted.***

V2.01.101 document***

***SDL101 - Simple oscillator under excitation  
random***

***Summary:***

***An oscillator simple, made up of a mass connected to a support by a spring and a shock absorber, is subjected to a random excitation transmitted by the support, of imposed acceleration type.***

***This test uses the functionalities of the stochastic analysis and calculates the spectral concentration of power (DSP) movement of the mass starting from the excitation of the white vibration type data by its DSP also.***

***The movement is calculated according to various options: relative, absolute, differential movement.***

***One calculates then the statistical properties of the response while passing in all the options of random dynamic postprocessing.***

***Handbook of Validation  
V2.01 booklet: Linear dynamics of the discrete systems

***Problem of reference***

***1.1 Geometry***

**AX**

**K**

**DX**

**m**

***The excitation is a seismic movement of type imposed acceleration AX applied to the support in feel DX.***

***One is interested in the movement of the mass Mr.***

**1.2**

***Material properties***

***Specific mass:***

***m = 100 kg***

***Arises elastic:***

***K = 105 N/m***

***Modal damping:***

$0 = 0.05$

### 1.3

#### **Boundary conditions and loadings**

*The problem is unidimensional in direction X, and to 1 degree of freedom: the displacement of mass Mr.*

*The excitation is a spectral concentration of power (DSP), of constant acceleration between 0. and 100 Hz.*

*It is applied to the support.*

### **Summary of the results**

*It is not astonishing that the results awaited for the random dynamic response are obtained with an accuracy of 0%. Indeed the DSP of the answers do not result from an iterative process of resolution, but of an analytical expression bringing into play the modal transfer transfer functions. This analytical expression coincides with the reference solution for this problem.*

*For postprocessing, there is no reference solution. The results of version 4.03.09 are used to check that the results do not evolve/move from one version to another. Calculation has very well supported the change of platform.*

**Handbook of Validation**

**V2.01 booklet: Linear dynamics of the discrete systems**

**Document: V2.01.102**

**SDL102 - Under transitory structuring:**

**System 3 masses-4 springs**

**Summary:**

*The applicability of this test relates to the dynamics of the structures. It makes it possible to validate the diagram*

*of integration to step of adaptive time of operator DYNA\_TRAN\_MODAL [U4.54.03] as well as the calculation of*

*linear transitory response on a modal basis calculated by under-structuring (for the 4 diagrams of integration of DYNA\_TRAN\_MODAL: "EULER", "DEVOGE", "NEWMARK" and "ADAPT"). In particular, the case of*

*the application of a damping reduced to the dynamic modes of the bases of projection of the substructures is treaty.*

*It is a question of determining the transitory response of a system made up of 3 masses and 4 springs, embedded with its*

*ends and subjected to a constant force as from the initial moment. The springs are modelled by elements of the type "DIS\_TR" and masses by elements of the type "DIS\_T".*

*Three modelings are proposed. In the 2 first, the structure is not deadened. Methods of calculation transient by under-structuring with interfaces of the type Craig-Bampton ("CRAIGB") and Mac Neal ("MNEAL") are*

*tested. The results of reference which are associated for them result from an analytical calculation. In the third,*

*one imposes a reduced damping of 1% on the dynamic modes of the bases of projection of*

*substructures. The transitory equation checked by the complete structure was obtained analytically. Its resolution, which acts as reference, was carried out by the Maple software.*

## **7 Modeling**

**C**

### **7.1**

#### **Characteristics of modeling**

The clean modes of the complete system are calculated by using the method of calculation modal by under-structuring with interfaces of the type “Craig-Bampton” (blocked interfaces). Bases of each substructure are made up of a dynamic mode and a constrained mode.

With the dynamic mode of each substructure a damping reduced with 1% is associated.

The transitory response of the deadened system is calculated on the modal basis calculated by under-structuring.

The steps of time taken are equal to: 102 S in “ADAPT”, 102 S in “EULER”, 102 S in “NEWMARK”.

### Summary of the results

The precision on displacement, the speed and the acceleration of the node  $x_2$  at the moment  $T = 80$  S is excellent (relative error < 1%).

This test thus validates the operators of calculation of transitory answer linear on calculated modal basis by dynamic under-structuring (with and without damping), as well as the diagram of integration with no the adaptive time of operator DYNA\_TRAN\_MODAL.

**SDL103 - Seismic response of a system  
3 masses and 4 springs multimedia**

## Summary

The problem consists in analyzing the response of a mechanical structure of embed-embedded beam type and not deadened, modelled by a system 3 masses and 4 springs and subjected to a seismic loading unspecified.

One tests the discrete element in traction and rotation, the calculation of the clean modes and the static modes and calculation transitory response by modal superposition of a structure subjected to a accélérogramme of translation (modeling A) or of rotation (modeling B).

The results obtained are in very good agreement with the results of reference (analytical results).

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**The problem consists in calculating the response of a system to five degrees of freedom subjected to two**

**accelerations (**

**1 T) and (**

**2 T) distinct of an unspecified form. It is explained in detail in the reference**

**[bib2].**

**One calculates the Eigen frequencies initially  $f_i$ , the standardized associated clean vectors compared to modal mass  $N_i$  and the static modes of the system (analytical values). One calculate then the generalized response of the system multimedia while solving analytically the integral of Duhamel [bib1]. Lastly, one restores on the physical basis the vector of displacements relative (on the active degrees of freedom)  $X_r$ , which allows us, after having calculated the vector of displacements of drive  $X_e$ , to calculate the vector of absolute displacements**

**Handbook of Validation**

**V2.01 booklet: Linear dynamics of the discrete systems**

**V2.01.104 document**

**SDL104 - Extrapolation of local measurements  
on a complete model (discrete)**

**Summary:**

**It is about a test of linear dynamics discrete.**

*The goal is to test order PROJ\_MESU\_MODAL in the case of a discrete system. This order allows to project experimental dynamic transitory answers in a certain number of points on a modal base of a numerical modeling.*

*This test contains 2 modelings:*

*·  
projection is done on a basic concept modal of type [mode\_meca],*

*·  
projection is done on a basic concept modal of type [base\_modale].*

*For 2 modelings, provided experimental measurements are identical and make it possible to test seek nodes in opposite, the taking into account of a local orientation and the treatment of one sampling in constant time or not, for measurements in displacement.*

*In both cases, the reference solution is analytically given (by Maple); projection is realized in the favorable configuration where the number of modes is equal to the number of measurements.*

*The answers in displacement obtained after projection are identical to displacements of reference provided in data.*

*The values speeds and the accelerations deduced from the displacements obtained after projection are close relations of those obtained analytically. The weak noted variations are due to the errors of approximation*

*generated by the determination via a linear diagram in time of speeds and accelerations.*

## ***Problem of reference***

### ***1.1***

#### ***Description of the system***

*We consider the system represented by the diagram below:*

*K*

*K*

*K*

*m*

*m*

*X1*

*X2*

### ***1.2***

#### ***Masses and rigidity***

*The three springs are of identical rigidity:  $K = 1000 \text{ N/m}$ .*

*The two masses are equal to  $m = 10 \text{ kg}$ .*

### ***1.3***

#### ***Boundary conditions and loading***

*The two ends are embedded.*

*The loading is a thrust load in traction applied to the mass  $m1$ , sinusoidal according to time, of pulsation.*

*Handbook of Validation*

**2**

***Reference solutions***

**2.1**

***Method of calculation used for the reference solution***

*The analytical solution of this problem is presented below.*

*Modes and frequencies of vibration:*

*The following system characterizes the dynamics of the masses:*

$$m\ddot{x} + 2kx - kx$$

$$1$$

$$1$$

$$2 = 0$$

***éq 2.1-1***

*MX*

$$\ddot{x} + 2kx - kx$$

$$2$$

$$2$$

$$1 = 0$$

*What is equivalent to the following system:*

$$\begin{pmatrix} m & x \\ & \end{pmatrix} + X$$

$$\begin{pmatrix} 1 \\ & \end{pmatrix} + K (X + X$$

$$\begin{pmatrix} 1 \\ & \end{pmatrix} = 0$$

**éq 2.1-2**

$$\begin{pmatrix} m & x \\ & \end{pmatrix} - X$$

$$\begin{pmatrix} 1 \\ & \end{pmatrix} + K$$

$$\begin{pmatrix} 3 & (X - X \\ & \end{pmatrix} = 0$$

The 2 Eigen frequencies of the system are thus given by:

$$\frac{K}{m}$$

$$\frac{K}{m}$$

$$=$$

and

$$\frac{3K}{m}$$

$$\frac{K}{m}$$

$$=$$

**éq 2.1-3**

$$m$$

$$m$$

and the associated modal deformations are:

$$\begin{pmatrix} 1 \\ & \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ & \end{pmatrix}$$

*The checked dynamic system is as follows:*

**$MX$**   
& +  **$KX = F$**

**éq 2.1-6**

*While projecting on the basis of clean mode, we obtain:*

$$T \& + T = T$$

**M**

**K**

**F**

**éq**

**2.1-7**

*That is to say:*

$2m$

$0 \& 2k$

$0 \ 1 \ 1 \ 1$

$1$

$1$

$+$

$=$

$($

$\sin T$

$)$

**éq**

**2.1-8**

$0$

$2m \& 0 \ 6k \ 1 - 10$

$2$

$2$

*We thus end to the following uncoupled system:*

$1$

$m$

$\& + K = if($

$NT$

$)$

$1$

$1$

$2$

**éq**

**2.1-9**

*l*

*m*

**& + K**

**3 =**

(

*sin T*

)

2

2

**2.2**  
***Results of reference***

*The comparison of the results relates to displacements, speeds and accelerations along the axis of two masses, at five different moments.*

**2.3**  
***Uncertainty on the solution***

*The reference solution is exact.*  
*The discrete model represents perfectly the problem arising (the modal base is complete; there is not thus not of approximation related to a possible modal truncation). The number of modes of the base of modal projection is equal to the number of measurements, therefore the solution of the inversion is exact (by*

*opposition to an approximate solution of a generalized opposite problem). If the research of the nodes in opposite is good, the displacements obtained after projection must be in perfect adequacy with the experimental values. Speeds and accelerations are determined by derivation of modal contributions identified via a diagram of linear approximation in time, thus being able to generate some errors.*

*The sampling of time is variable: every moment is indicated of 0 S to 1 S, by step of 103 S (1001 moments on the whole).*

*The values result from the analytical calculation carried out with Maple.*

## 5.3

### *Characteristics of the modal base*

*The two only modes are stored in a concept of the type [base\_modale], created by the order DEFI\_BASE\_MODAL. The interface, of Craig-Bampton type, is placed on the degree of freedom in displacement following X of the node N2 (corresponding to the mass m 1). The modal base thus contains a dynamic mode (with blocked N2) and a static mode.*

**Summary of the results**

***For two modelings, the answers in displacement obtained after projection are identical with the displacements of reference calculated analytically with Maple and provided in data.***

***Values speeds and the accelerations deduced from the displacements obtained after projection are close to those obtained analytically. The weak noted variations are due to the errors of approximation generated by the determination by a linear diagram in time speeds and accelerations.***

***SDL313 - System masses spring with 2 DDL with  
damping hysteretic***

***Summary:***

***This one-way problem consists in carrying out a harmonic analysis of a mechanical structure composed of a whole of mass-springs with damping hysteretic and subjected to an excitation sinusoidal. This test of mechanics of the structures corresponds to a dynamic analysis of a discrete model***

***having a linear behavior. It includes/understands three modelings.***

***Via modeling A, one tests the discrete elements in translation (mass, arises), them options AMOR\_HYST of AFFE\_CARA\_ELEM.***

*Via modeling B, one tests the elements of beam (POU\_D\_T), options AMOR\_HYST of DEFI\_MATERIAU,*

*Via modeling C, one tests calculation modal (MODE\_ITER\_SIMULT) complex.*

*On the first two modelings, one tests the definition of a force of specific excitation harmonic and the operator of harmonic calculation of answer (DYNA\_LINE\_HARM [U4.54.02]). In addition, several are tested*

*operators of postprocessing: RECU\_FONCTION [U4.62.03], TEST\_FONCTION [U4.72.02], RECU\_CHAMP [U4.62.01].*

*Results obtained for the first two modelings (field of displacement for different frequencies of excitation) are in concord with the results of guide VPCS. Results obtained for the third modeling are in concord with the semi-analytical results.*

***V2.01.320 document***

***SDLD320 - Transitory response of a free system  
of 3 masses and 2 springs under excitation  
harmonic***

***Summary:***

***One considers the transitory analysis of a discrete system masses/arises linear with three degrees of freedom completely free. This system has a non-proportional damping. A sinewave excitation is applied at an end of the system.***

***In this problem, one tests, through a discrete model, the calculation of the transitory response of a system whose rigid modes are not fixed. One is interested only in the transient state. For that, one will seek the solution by an integration on the complete modal basis (DYNA\_TRAN\_MODAL [U4.53.21]).***

*The results obtained (displacement, speed and acceleration) are compared with an average of results coming from industrial codes and a method of integration numerical of type - Newmark improved.*

## 2

**Reference solution**

## 2.1

**Method of calculation used for the reference solution**

The research of the transitory response of this problem to damping nonproportional, and where the rigid modes are not fixed, can be carried out by numerical integration in real space:

$$[M] \{\ddot{u}\} + [C] \{\dot{u}\} + [K] \{U\} = \{F\}$$

$$N$$

$$N$$

$$N$$

$$\}.$$

For that, the answer was calculated with two industrial codes:

.

PERMAS: Diagram of integration of Newmark ( $\gamma=0,25$ ,  $\beta=0,5$ ),  $t=104s$ ,

Diagram of integration with cubic interpolation of Hermit [bib1],  $t=104s$ ,

.

ABAQUS: Diagram of integration of Hilber-Hughes-Taylor [bib2] ( $\alpha=-0,05$ ),  $t=104s$ ,

and method of integration of - Newmark improved [bib3]:

$$[M] [C] [K]$$

$$+$$

$$+$$

$$+$$

$$+$$

$$+$$

$$+$$

$$\{$$

**5**

**Summary of the results**

**.**

**To obtain a good precision of the results, it is initially necessary to obtain a base modal precise and perfectly orthogonal (MODE\_ITER\_SIMULT):**

**by avoiding the multiple modes (different rigidity on the nonexcited ddl),**

**by calculating the rigid modes of body correctly (to prefer the option “Centers” in MODE\_ITER\_SIMULT with the other options),**

**by specifying method “JACOBI” for a modal complete extraction.**

**.**

**The precision of the results is good as well for displacements for speeds and accelerations.**

**For the elastic response of the system (relative displacements  $u_3-u_1$ ), the numerical precision is one little worse because of the numerical office plurality of the errors on the absolute values.**

***SDL321 - Transitory dynamic response of one harmonic oscillator with damping variable***

***Summary:***

***The system considered is a harmonic oscillator with 1 d.d.f under harmonic excitation with resonance.***

***Various depreciation will be considered:***

- .  
critical damping,***
- .  
average damping,***
- .  
very weak damping.***

***Via this problem, one tests the various algorithms of order DYNA\_TRAN\_MODAL [U4.54.03] and their capacities to deal with problems with extreme damping. The results are compared with the exact analytical solutions.***

## **4.2 Remarks**

*The results are tested on the level of the peaks for the grain of observation selected (10-2s) where values are most significant.*

*The mode becomes quasi-permanent after the first period, it is what one must observe in carrying out a transitory analysis.*

## **6.2 Remarks**

*The results are tested on the level of the peaks where the values are most significant.*

*The duration of selected observation makes it possible to see the effect of damping. However, in this interval, the response of the point B remains always transitory but one is close to steady operation whose scale of displacement is  $10^{-2}m$ .*

***11/12***

**9**

***Summary of the results***

***As modeling A, as result obtained as well in displacement of speed have an error absolute largely lower than 1% compared to the analytical solution.***

***The diagram of integration of Newmark is shown more precise than the diagram of Euler.***

***To 1% of damping criticizes (modeling B), the diagram of Fu-Devogelaere integration is of one frightening precision (not of error compared to the reference solution).***

***The diagram with step of adaptive time also gives results to very small percentage of error.***

***For very weak depreciation (modeling C), one will note a better precision for diagram of integration of the Euler type that for a diagram of the Newmark type. For this last, the error increase according to time but remains lower than 1% all the same.***

***SDLD325 - Transitory dynamic response of one system mass-arises deadened to 2 ddl***

***Summary:***

***This problem consists in analyzing the dynamic response of a system made up of a unit of mass-spring-shock absorbers with 2 ddl from which the stiffnesses of the springs are very different under excitation from crenel type in 1 ddl.***

***Via this problem, one tests the sensitivity of diagrams of integration on physical space (DYNA\_LINE\_TRAN [U4.53.02]) or modal space (DYNA\_TRAN\_MODAL [U4.53.21]) with respect to the report/ratio of rigidities.***

***The results in displacement and speed are compared with an average of results coming from codes industrialists and of a method of integration numerical of type - Newmark improved.***

*SDLL01 - Short beam on simple supports*

**Summary:**

*This two-dimensional problem consists in seeking the frequencies of vibration of a mechanical structure*

*composed of a beam in simple supports at its two ends. This case test of Mechanics of the Structures corresponds to a dynamic analysis of a linear model having a linear behavior. One studies the influence of the position of the points considered as points of supports (points on neutral fibre or points*

*offset at the base of the beam) compared to neutral fibre of a thick beam.*

*This test which comprises only one modeling, makes it possible to test part of the functionalities which concern the beams of Timoshenko, the connections rigid and the search for Eigen frequencies by iterations*

*opposite.*

*Results obtained, either with the points of supports on neutral fibre, or with the points of offset supports*

*are compared with results VPCS. In the second configuration, the reference solution is an average results of several software packages.*

*When the points of supports are offset, one observes a coupling between the various modes of traction and compression and of inflection.*

***Handbook of Validation***

***V2.02 booklet: Linear dynamics of the beams***

***V2.02.002 document***

***SDLL02 - Beam hurled, embed-free,  
folded up on it even***

***Summary:***

***This two-dimensional problem consists in seeking the frequencies and the modes of vibration of a structure mechanics, made up of a hurled, embedded beam free and folded up on itself.***

***The problem arising does not have physical significance. It on the other hand makes it possible to validate the research of Eigen frequencies of inflection multiples and the research of the modes double in a subspace of order 2.***

***In this test, one carries out three different modelings:***

- in the first modeling, the boundary conditions are imposed using parameters of Lagrange (order AFFE\_CHAR\_MECA) and the clean values and vectors are calculated by method of Lanczos (order MODE\_ITER\_SIMULT, method: "TRI\_DIAG"),***
- in the second modeling, the boundary conditions are imposed by removing degrees of freedom in the matrices of mass and stiffness (order AFFE\_CHAR\_CINE) and the values and clean vectors are calculated by the method of Bathe and Wilson (order MODE\_ITER\_SIMULT, method: "JACOBI"),***
- in the third modeling, one checks the behavior of modeling COQUE\_C\_PLAN in dynamics. The eigenvalues and the clean modes are calculated with the order MODE\_ITER\_SIMULT and with the method of SORENSEN.***

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

***The reference solution is that given in card SDLL02/89 of the guide VPCS which presents method of calculation in the following way:***

***By the method of stiffness dynamic, one shows that the folded up beam admits frequencies double, solution of:***

***cos***

***() = 0***

***I = 2***

***(I - 1) 2***

***2***

***E I***

***F***

***I***

***Z***

***I = 1***

***I = 1, 2, ...***

***2 L2***

***With***

***For a rectangular section, one obtains:***

***E***

***F***

(  
 ) 2  
 $I = 2 I - 1 R$   
 $I = 1, 2, \dots$   
 8 L2  
 12

*This formulation neglects the deformations of shearing action and inertia of rotation (beam of Euler-Bernoulli).*

*For the clean modes, the forms are given in guide VPCS. They are normalized to 1 or 1 with not greater amplitude. There are results only for modes 1, 2, 3, 4, 7 and 8. By example, the forms of the first two clean modes are as follows:*

1  
 1  
 0.707  
 0.707  
 mode 1  
 F  
 mode 2  
 $f_1 = 11.76 \text{ Hz}$

## 2.2 Results of reference

*The results of reference are the first eight Eigen frequencies and displacements of the points B, C for the clean modes 1, 2, 3, 4, 7 and 8. In Code\_Aster, the modes are normalized to 1 with not greater amplitude (order NORM\_MODE). To be able to make comparisons with the results of reference, the latter were corrected (multiplication by 1 if necessary).*

## 2.3 Uncertainty on the solution

*There is no uncertainty on the solution because it is analytical.*

## 9

### **Summary of the results**

· *Modélisations A and B of the Beam type:*

*The problem is dealt with with very good precision on the first eight frequencies (tolerance < 0.1%) for two modelings tested. The components of modes 3, 4, 7 and 8 are also obtained with a good precision of about 0.1%. The precision on mode 1 is of the order of 1% for the method of Lanczos and 0.5% for the method of Bathe and Wilson. In it who relates to mode 2, the precision degrades himself: it is about 2.7% for the method of Lanczos and about 3.3% for the method of Bathe and Wilson. Complementary tests (use of the method of Lanczos by imposing boundary conditions by the order AFFE\_CHAR\_CINE) make it possible to think that these differences come from the method of seek eigenvalues used.*

· *Modélisation COQUE\_C\_PLAN*

*The precision on the results is good for the first three frequencies, the error is of the order from 0.6%. It is degraded as the frequency increases, the error passes from 4th frequency with 8th of 1.5% to 6.4%. More the frequency is high plus the difference between the frequencies double is important. The error on the modes is satisfactory for the first 7 modes (<0.7%), it is higher for 8th (<4%). A finer grid should allow best to represent the modal deformations associated with the high frequencies.*

***SDLL04 - Beam hurled on two supports,  
coupled to a system mass-arises***

**Summary:**

*This plane problem consists in seeking the frequencies of vibration of a mechanical structure made up of one*

*beam embed-slide and of a mass connected to the beam by a spring. Stiffness of the spring and mass depend on a variable parameter, which will make it possible to highlight the displacement of the frequencies*

*clean for a small disturbance of the model. This test of Mechanics of the Structures corresponds to an analysis*

*dynamics of a linear model having a linear behavior. It includes/understands only one modeling.*

*This problem makes it possible to test the element of beam of Timoshenko in inflection, the calculation of the Eigen frequencies*

*by the method of the iterations opposite and the method of Lanczos, the discrete elastic connection between one*

*specific mass and a node of a beam.*

*The results obtained are in concord with the results given in guide VPCS. It well is observed unfolding of the Eigen frequencies induced by the disturbance of the initial model (beam hurled on two supports).*

7

***Summary of the results and remarks general***

***The simplified model presented in this case test makes it possible to validate the method of numerical resolution.***

***To deal with the real physical problem, it would be necessary to take into account the effects of inertia (mass of post, effect of inertia of rotation around B of the superstructure) and of compression of the post (actual weight).***

***For modeling A, the error made with a step of time of 5. 104 S is about 0,01%; for modeling B (not of times of 103 S) it is about 0,6%.***

***One will be able to supplement this case test by checking the convergence of the results for other step values time and by comparing the results obtained with other diagrams of integration.***

## ***SDLL08 - Fit latticework on plane beams***

***(metal sections)***

### ***Summary:***

***This three-dimensional problem first of all consists in carrying out a modal analysis and then to study harmonic response of a mechanical structure of a plane netting of beams. This test of Mechanics of Structures corresponds to a dynamic analysis of a linear model having a linear behavior. It only one modeling includes/understands.***

***This problem thus makes it possible to test the element of beam of Euler Bernouilli in transverse inflection, the calculation of***

***frequencies and of the modes of vibration by the method of Lanczos and the use of linear relations enters***

***displacements of two points in modal analysis and harmonic answer.***

***The results are in agreement with the analytical results of guide VPCS.***

#### 4.2 Remarks

Calculations carried out by:

MODE\_ITER\_SIMULT METHOD: "TRI\_DIAG"

OPTION: "PLUS\_PETITE"

NMAX\_FREQ: 3

One obtains an antisymmetric mode for a frequency  $F = 22.5676$  Hz. This Eigen frequency depends on the constant of provided torsion; this one is not defined in the bench-mark data. Values WB/WG are not checked in the test but are obtained manually starting from WB and WG + WB.

Value (WG) max is not checked in the test. One has only access to WB max and (WB + WG) max. WG max is obtained manually by difference.

### **Summary of the results**

The values of the Eigen frequencies and the clean vectors are obtained with a precision  $< 0.3\%$ .

The variation of 2.5% on the maximum arrows at the points B and E would deserve to check the solution of

reference, to supplement the validation of the harmonic answer.

**SDLL09 - Vibration of a slim beam**

**of variable rectangular section (embed-free)**

**Summary:**

This plane problem consists in seeking the frequencies of vibration of a free fixed beam with section rectangular variable. This test comprises only one modeling.

The variation of section of the beam is either homothetic, or nonhomothetic. Characteristics of section of the beam are given according to meshes' in two different ways:

- section and inertias,
- height and width.

This problem thus makes it possible to thus test the element of beam with variable section for a prismatic structure that the calculation of the frequencies of vibration by iterations opposite. In addition, in the operator AFFE\_CARA\_ELEM [U4.24.01], one tests the remanence of certain key words. The results obtained are in concord with those given in guide VPCS.

**SDLL10 - Rectangular beam of section**

**variable (embed-embedded)**

**Summary:**

This plane problem consists in seeking the frequencies and the modes of vibration of a mechanical structure

composed of an embed-embedded beam whose surface of the cross-section varies exponentially. This test

of Mechanics of the Structures corresponds to a dynamic analysis of a linear model having one linear behavior. It includes/understands only one modeling.

Via this problem, one tests the element of beam in inflection of variable Timoshenko of section as well as the calculation of the frequencies and modes of vibration by the method of Lanczos. One also tests

functionality "normalizes to 1." at the point of maximum amplitude in translation " of the modes of vibration.

By using a fine space discretization, the results obtained are in concord with the results analytical given in guide VPCS.

**Summary of the results**

Suitable modeling (frequencies and modes suitable for less than 2%) with a fine grid.

A calculation carried out on a coarse grid (12 meshes) shows more important variations with reference solution. This is especially due to the way in which the modes are normalized.

***SDLL15 - Beam hurled, embed-free,  
with mass or offset inertia***

***Summary:***

***This three-dimensional problem consists in calculating the frequencies and the modes of vibration of a structure***

***mechanics made up of a right beam slim, embed-free, with tubular section and of a mass offset attached at the loose lead of the beam. This test of Mechanics of the Structures corresponds to one***

***analyze dynamic of a linear model having a linear behavior. It comprises only one modeling.***

*This problem makes it possible to test the element of beam of Euler Bernouilli, the model of specific mass and calculation*

*modal by the method of Lanczos.*

*The results obtained are in concord with those of guide VPCS. Two calculations carried out (eccentricity of*

*the specific mass null or different from zero) make it possible to highlight the coupling of different modes when the specific mass is offset.*

### ***Reference solution***

#### ***2.1***

#### ***Method of calculation used for the reference solution***

***The reference solution is that given in card SDLL15/89 of the guide VPCS which presents method of calculation in the following way:***

***The problem with not offset mass leads to uncoupled modes:***

- traction and compression (effect of the mass alone),***
- torsion (effect of inertia around neutral fibre),***
- inflection in plans X, y and X, Z (effect of the mass).***

***The various Eigen frequencies are given with a model by finite elements of beam of Euler (slim beam).***

***For the first mode with an unbalance, a method of Rayleigh gives the formula approached:***

***3rd I***

***F = 1***

***Z***

***1***

***2***

***L3 m***

***( +***

***)***

***C***

***0.24 M***

***with M = total mass of the beam.***

***When the mass is offset, the modes of inflection (X, Z) and of torsion are coupled, as well as modes of inflection (X, y) and of traction and compression.***

***For the clean mode, the components at the point B make it possible to calculate the components in the center***

**Summary of the results**

The modeling of unbalance gives exact results for the 8 frequencies of reference.

The precision of the clean modes is about 0.1% until mode 4.

**SDLL23 - Subjected embed-free beam**

**with a seism (spectral answer)**

**Summary**

This one-way problem consists in carrying out a spectral seismic analysis of a free fixed beam provided with two localised masses subjected to a three-dimensional excitation provided in the shape of a spectrum

oscillators in pseudo-acceleration.

Via this problem, one tests modal combinations DPC, SRSS, CQC and DSC of the operator COMB\_SISM\_MODAL [U4.54.04]. Combination SRSS is tested with taking into account of the neglected modes.

In addition, one tests the operators of preprocessing MODE\_ITER\_SIMULT [U4.52.02], NORM\_MODE [U4.64.02], MODE\_STATIQUE [U4.52.04], DEFI\_FONCTION [U4.21.02] and DEFI\_NAPPE [U4.21.03]. The results obtained are in agreement with the card of validation suggested in guide VPCS.

**SDLL100 - Transitory dynamic response  
of a beam in simple traction**

**Summary:**

This problem-test corresponds to a direct transitory analysis of a deadened linear system or not, made up of a beam in simple traction, subjected to a loading of the Heaviside type applied as from the initial moment.

The problem discretized with 1 single element of beam has an analytical reference solution.

### **Summary of the results**

The two algorithms give a solution with an error lower than 0.2% of the solution of reference after the first two steps of time.

This problem requires a step of time of integration of 105 S.

## **SDLL101 - Vibration of a beam with prestressed**

### **Summary:**

This plane problem consists in seeking the frequencies of vibration of a mechanical structure made up of one

hurled beam, of circular section, under tension embed-slide. This test of Mechanics of the Structures corresponds to a dynamic analysis of a linear model having a linear behavior. This test comprises two modelings.

In the first modeling, one tests the element of beam of Timoshenko subjected to a prestressing, it calculation of geometrical rigidity and the calculation of the Eigen frequencies by the method of Lanczos. In

the second modeling, one tests the element of beam of Euler-Bernouilli subjected to a prestressing, the calculation of

geometrical rigidity and the calculation of the Eigen frequencies by the method of Bathe and Wilson.

The results obtained are in concord with the results of guide VPCS. One notices a shift towards high frequencies of vibration when prestressing in the beam increases.

**SDLL102 - Gantry subjected to electrodynamic forces**

**Summary:**

This test is a three-dimensional problem of direct transitory dynamic calculation with forces distributed of electrodynamic origin applied to a gantry (bars on 3 insulating columns of a station of transformation).

This test was provided by the Center of Studies of the Grid system (EDF-DEPT). It was supplemented

since by  
a benchmark international bench starting from experimental measurements (results of several foreign codes):  
test CIGRE-structure D.  
It makes it possible to compare results of displacements compared to those obtained by other industrial codes  
using a finished method finite elements or differences.  
This test contains a modeling with elements of the type SEG2.

**Summary of the results**

The results are acceptable compared to the test results and locate values produced by Code\_Aster in good place among ten results of other software.

The values of reference of the file of test are those of version 3.04.02 of the code (not regression).

V2.02 booklet: Linear dynamics of the beams  
V2.02.104 document***

***SDLL104 - Structures primary education and secondary  
subjected to a random excitation***

***Summary:***

***A principal beam of strong rigidity and important mass (primary structure), embedded at its base, support in three points of transmission of efforts a light and flexible beam (secondary structure).***

***The primary structure is excited at its base by an acceleration given by its DSP.***

***The test compares a direct calculation of the whole of the two structures and a chaîné calculation where the answer of principal beam at the points of connection is used like the excitation of the secondary beam.***

***The following functionalities are tested:***

***.  
stamp interspectrale analytical preset by the function of KANAI-TAJIMI,***

***.  
random dynamic response moving absolute, imposed acceleration,***

***.  
modal answer interspectrale,***

***.  
modal excitation interspectrale.***

*This approach is representative of what is required for the industrial studies: to determine them answers of various secondary structures knowing the answer of the primary structure.*

**Young modulus beams A and b:**

**$E = 2.1 E+11 \text{ N/M}^2$**

**Poisson's ratio beams A and b:**

**$= 0.3$**

**Density beam Pa:**

**$With = 2000 \text{ kg/m}^3$**

**Density beam PB:**

**$B = 1000 \text{ kg/m}^3$**

**1.3**

**Boundary conditions and loadings**

**The movement is authorized in the plan (DX, DY).**

**Beam Pa is embedded in the support.**

**The beam PB is connected to beam Pa by three points. In each one, displacements in direction DX and DY of the node of Pa and the PB node are identical. Rotations are not dependent.**

**The matrix interspectrale which transmits displacements of structure Pa to the structure PB in chained calculation is of dimension 6 (6 ddl of transmission).**

***SDLL105 - Pipe subjected to sources  
random fluid excitations***

***Summary:***

*A right piping embedded at an end in the wall of a tank and supporting a mass with the other end is subjected to a fluid excitation.*

*The excitation is defined by its spectral concentration of power in the form of a “white vibration”.*

*It covers all the types of source established in the code:*

- *source of flow-volume,*
- *source of flow-mass,*
- *source of pressure,*
- *source of force,*
- *imposed effort.*

*One is interested in the spectral concentration of power of the response in a degree of freedom of pressure located on node supporting the mass.*

*The random dynamic response is given here moving absolute.*

**SDLL106 - Beam subjected to an excitation**

## ***random distributed***

### ***Summary:***

***An Bi-embedded beam is subjected over all its length to an effort distributed. Profile of distribution of the force is identical to all the frequencies.***

***The random movement of this beam is evaluated by a stochastic approach: the density is determined spectral of power of displacement in various points of the beam.***

***The two possibilities are tested:***

- .  
space function of the efforts applied with interspectre unit (method 1),***
- .  
interspectre builds directly for the excited ddl (method 2).***

***This test is an illustration of the response of a structure subjected to a Eolienne excitation.***

### ***Summary***

*This multidirectional problem consists in carrying out a spectral seismic analysis of a made up structure elements of beams without masses and discrete masses to the nodes. It includes/understands two*

*modelings*

*correspondent with two smoothnesses of discretization.*

*The seismic excitation is provided in the shape of three spectra of response of oscillators in acceleration to*

*supports according to axes' X, Y and Z.*

*Via this problem, one tests order MODE\_STATIQUE [U4.52.04] and the options of quadratic combination of the modes and quadratic combination of the directions of the excitations of order COMB\_SISM\_MODAL [U4.54.04].*

*The results obtained are in concord with the results of reference.*

***V2.02 booklet: Linear dynamics of the beams***  
***Document: V2.02.113***

***SDLL113 - Under-structuring dynamic  
transient: beam in simple traction***

***Summary:***

***The structure considered is an annular beam of section in simple traction, embedded on a side, and subjected at its end with a force of the Heaviside type. Its transitory dynamic response is calculated by under-structuring.***  
***The beam is modelled by elements of the beams type of Timoshenko (linear model). Two modelings are proposed according to whether the beam is deadened or not. Damping tested is of type RAYLEIGH (damping proportional).***  
***The results of reference result from a direct transitory calculation by modal recombination without under-structuring with operator DYNA\_TRAN\_MODAL [U4.54.03]. This test thus makes it possible to validate the tools of transitory calculation of response per under-structuring, in the linear case.***

**4.2 Remarks**

*One can be astonished that the adopted reference corresponds to the complete beam modelled by 10 elements and not with the analytical solution. It is that the development of the solution in series of clean modes converges very slowly: the modal solution is very far away from the solution here theoretical. The relevant comparison is thus well that selected.*

*Calculation by modal recombination is carried out on the basis of complete modal structure (11 modes) taking into account the adopted discretization. In the same way, the dimension of the base of projection used for calculation by dynamic under-structuring 11 (substructure of left is: 4 modes clean + 1 constrained mode; substructure of right-hand side: 5 clean modes + 1 constrained mode). It is thus normal to obtain an excellent agreement between the modeling of the complete beam and that of beam divided into two substructures.*

## 5.1

### *Characteristics of modeling*

*The characteristics of this modeling are identical to the preceding one (modeling A). Only difference lies in the fact that the structure is deadened. Damping used is of type proportional:*

$$C = K + M \text{ with } = 6.5 \times 10^6 \text{ S and } = 16.0 \text{ s1.}$$

*These values correspond to a reduced damping of 1% on the first mode of the structure.*

## 5.2

### *Characteristics of the grid*

*The characteristics of the grid are also identical to those of modeling A (cf [§ 3.2]).*

## 6.2 Remarks

*One can be astonished that the adopted reference corresponds to the complete beam modelled by 10 elements and not with the analytical solution. Important differences between the numerical solutions and theoretical are ascribable with the reduced number of elements. The use of 50 elements instead of 10 would have allowed to approach theoretical acceleration with a margin of 1%. That put aside, one can note that the use of a method of under-structuring provides the same results as those of the beam complete.*

*Calculation by modal superposition is carried out on the basis of complete modal structure (11 modes). In the same way, the dimension of the base of projection used for calculation by under-structuring dynamics is 11 (substructure of left: 4 clean modes + 1 constrained mode; substructure of right-hand side: 5 clean modes + 1 constrained mode). It is thus normal to obtain an excellent agreement enters the modeling of the complete beam and its modeling in two substructures.*

## **Summary of the results**

*As well in the case not deadened as in the deadened case, the results obtained using the model complete and by under-structuring do not present significant variations. Operators of calculation linear transient by under-structuring are thus validated.*

*In the deadened case, the agreement between the solutions numerical and analytical would have been better while taking more elements (50 instead of 10 for example).*

*Lastly, let us announce that the results obtained by Code\_Aster were compared with results obtained by the SAMCEF software. They are included in the table below. One notes that in the case not deadened, the two software provides nearby results, quite as far away from the solution analytical.*

## ***SDLL118 - Beam subjected to an excitation fluid-rubber band axial***

### ***Summary:***

***One considers a PVC tube placed at the center of a cylindrical enclosure of section circular and subjected to the action of an axial water flow. This hardware configuration corresponds to the experimental device of Tanaka and Al [bib1] which is used to measure the evolutions of frequency and reduced damping of the first mode tube according to the mean velocity of the flow.***

***The goal of this case-test is to validate the resorption of model MEFISTEAU [R4.07.04] making it possible to calculate them modal characteristics of a telegraphic structure under confined axial flow, by taking account of one excitation of the fluid-rubber band type.***

***The functionalities particular to test are as follows:***

- operator DEFI\_FLUI\_STRU [U4.25.01]: definition of the parameters for the taking into account of coupling fluid-rubber band, in the case of a configuration of the type “beam of tubes under axial flow” (key word factor FAISCEAU\_AXIAL),***
- operator CALC\_FLUI\_STRU [U47.66.02]: calculation of the evolutions of the frequencies and depreciation modal tiny rooms according to the mean velocity of the flow, by the implementation of the model MEFISTEAU.***

***The numerical results of the simulation of the device of Tanaka and Al are validated by comparison with experimental results. Taking into account relatively important uncertainties on the values experimental, the results of reference for nonthe regression of the code are those obtained numerically during the restitution of the case-test.***

***Problem of reference***

***1.1 Geometry***

*The tube considered is a hollow roll whose characteristic dimensions are as follows:*

*length*

*L*

*= 1 m,*

*external diameter*

*ext. = 13 mm,*

*internal diameter*

*int = 8,8 Misters.*

*The tube is placed in the center of a cylindrical enclosure of circular section. The internal diameter of the enclosure is worth  $D = 5$  cm.*

*The surface roughness of the tube is worth = 105 Mr.*

**1.2**

***Properties of materials***

*The physical characteristics of material PVC constituting the tube are as follows:*

*Young modulus*

*$E = 2,80. 10^9$  Pa,*

*Poisson's ratio = 0,3,*

*density*  
*= 1500 kg/m<sup>3</sup>.*

*Water surrounding the tube has the following properties:*

*density*  
*water = 1000 kg/m<sup>3</sup>,*  
*kinematic viscosity water = 1,1.106 m<sup>2</sup>/s.*

### **1.3** ***Boundary conditions and loadings***

*The two ends of the tube are connected to fixed supports by two metal stems. The relative one flexibility of inflection of these stems releases the degrees of freedom of rotation of the ends of the tube. One can thus estimate that the conditions of self-supporting quality of the tube are of the rotulé-rotulé type, the stems metal introducing of each end an additional stiffness of rotation.*

*Moreover, these stems make it possible to apply an axial load to the tube, which can thus be prestressed in traction or in compression. In practice, two configurations are studied:*

- nonprestressed tube: no effort is applied. This configuration corresponds to modeling A of the case-test,*
- tube prestressed in compression by application of an axial load of 40 NR at an end.*

*This configuration corresponds to modeling B of the case-test.*

## **Reference solution**

*The experimental measurements taken on the device of Tanaka and Al provide the values of reference for the validation of the model.*

*Two graphs below, representing the evolutions of the frequencies and damping tiny room of the first mode doubles inflection according to the mean velocity of the flow, allow to compare the results of the model with the experimental results.*

*Taking into account uncertainties on measurements, the tolerance of relative variation for the validation of the model*

*is rather broad. This is why experimental measurements cannot be used as values of reference for the case-test, a narrower tolerance being necessary to guarantee nonthe regression of the code. values of reference used are thus those obtained numerically during the restitution of the case test.*

### **3 Modeling**

**With**

#### **3.1**

#### **Characteristics of modeling**

*The tube is represented by 100 elements of right beams of Timoshenko (MECA\_POU\_D\_T), supported per as many meshes segments to 2 nodes (SEG2). Two elements MECA\_DIS\_TR are additions with the nodes ends of the tube, allowing to model the metal stems by stiffnesses of rotation discrete.*

*One carries out with the elements of beam the characteristics of circular section:*

*external ray*

*Rext = 6,5.103 m,*

*thickness E*

*=*

*2,1.103 Mr.*

*(cf paragraph [§1.1])*

*One also assigns to these elements a material of behavior ELAS:*

*Young modulus*

*E = 2,80. 109 Pa,*

*Poisson's ratio = 0,3,*

*density*  
*= 1500 kg/m<sup>3</sup>.*  
*(cf paragraph [§1.2])*

*One assigns to the discrete elements the same stiffness of rotation around the two orthogonal axes to the neutral fibre of the tube:*

*Kr = 6,29 Nm/rad*

*This stiffness of rotation was adjusted in order to find the Eigen frequency of the first double mode in air.*

*The degrees of freedom in translation DX and DZ of the nodes ends N001 and N101 are blocked so to prohibit a rigid movement of body of the tube (axial translatory movement). One blocks also the DY of the N001 node. Moreover, in each node, one blocks the degree of freedom of rotation DRY, in order to prohibit any movement of torsion.*

*The tube is immersed in a cylindrical enclosure of 2,5 cm interior ray (cf paragraph [§1.1]). The profiles of density and kinematic viscosity of surrounding water are presumedly constant along the tube:*

*density*  
*water = 1000 kg/m<sup>3</sup>,*

*kinematic viscosity water = 1,1.106 m<sup>2</sup>/s.*  
*(cf paragraph [§1.2])*

*No axial load is applied to the tube which is thus not prestressed.*

*The evolutions of the frequency and the reduced damping of the first double mode of inflection are calculated for a beach mean velocities of flow from 0 to 8 m/s, by step of 1 m/s. One takes account of an initial reduced damping of the tube of the 4,8%.*

### **3.2**

#### ***Characteristics of the grid***

*The total number of nodes used for the grid is 101.*

*The meshes (of type SEG2) are 100.*

*The file of grid is with the format ASTER.*

### 3.3

#### **Stages of calculation**

*Validation of the operators of coupling fluid-structure, for configurations of the type “beam tubes under axial flow” is made in two principal stages.*

*The first consists in defining the parameters of taking into account of the coupling fluid-structure with operator **DEFI\_FLUI\_STRU** followed by key word **FAISCEAU\_AXIAL**.*

*The second is the calculation of the evolutions of modal frequency and reduced damping according to mean velocity of the flow, with operator **CALC\_FLUI\_STRU** and by the implementation of model **MEFISTEAU**.*

**8/10**

#### **5 Modeling**

## **B**

### **5.1**

#### **Characteristics of modeling**

*Modeling B is identical to modeling A (cf paragraph [§3.1]), but this time the tube is prestressed in compression.*

*An axial load of compression of 23,7 NR is applied to the node N101 end. The intensity of the effort has thus readjusted compared to the provided experimental value of 40 NR, in order to find correctly the value of frequency of the first mode doubles in air (cf paragraphs [§1.2], [§1.3]). It readjustment can apply by the summary modeling of the metal stems ensuring it self-supporting quality and the setting in compression.*

*One deduces from the nodal effort the vector of elementary efforts, then an assembled vector which is built according to the classification of the degrees of freedom of the tube. Static deformation due to the setting in compression is then obtained by multiplying the vector assembled by the reverse of the matrix of rigidity structural. Using this static deformation, one calculates then a stress field with elements, whose is deduced a geometrical matrix of rigidity. This one is then added to stamp structural rigidity in order to obtain the matrix of rigidity of the tube in compression, which is finally used for the calculation of the modes in air.*

*The evolutions of the frequency and the reduced damping of the first double mode of inflection are calculated for a beach mean velocities of flow from 0 to 8 m/s, by step of 1 m/s. One holds count of an initial reduced damping of the tube of 4,3%.*

### **5.2**

#### **Characteristics of the grid**

*The characteristics of the grid of this second modeling are the same ones as those of modeling A, is: 101 nodes used and 100 meshes of the type SEG2.*

*The file of grid is with the format ASTER.*

### **5.3**

#### **Stages of calculation**

*Just as for modeling A, the functionalities to be validated are those of the operators of coupling fluid-structure for configurations of the type “beam of tubes under axial flow” (cf paragraph [§3.3]).*

**Moreover, modeling *B* makes it possible to test other functionalities.**

**The first makes it possible to carry out the calculation of a field of displacements to the nodes by inversion of**

**stamp rigidity structural and product of the reverse by a vector of assembled effort, with operators *FACT\_LDLT* and *RESO\_LDLT*.**

**The second allows the calculation of a geometrical matrix of rigidity using a stress field with the elements, with the operator *CALC\_MATR\_ELEM*, option *RIGI\_GEOM*.**

**Results of modeling B**

**6.1 Values**

**tested**

*The tests relate to the frequency and the reduced damping of the first double mode of inflection of tube, at the mean velocity of flow of 0 m/s and 4 m/s. 2 types of test are carried out:*

- a test of comparison with experimental measurements,*
- a test to guarantee nonthe regression of the code.*

**6.1.1 Frequency of the first mode doubles inflection**

- Test of comparison with the experiment, at the rate of flow of 0 m/s:*

*The tolerance of relative variation compared to the reference is worth 0,1%.*

## 1.2

### **Material properties**

•  
**concrete:  $E = 37.272 \text{ MPa}$ ,  $\nu = 0.2$ ,  $\rho = 2400 \text{ kg/m}^3$**

•  
**steel:  $E = 200.000 \text{ MPa}$ ,  $\nu = 0.33$ ,  $\rho = 7800 \text{ kg/m}^3$**

•  
**damping: of type Rayleigh (K+M), with 5% on modes 1 and 2**

## 1.3

### **Boundary conditions and loadings**

**Simple support in b:  $D_y = 0$**

**Support “doubles” in a:  $dx = Dy = 0$**

**To avoid the clean modes except plan, one blocks the following degrees of freedom on all the beam:**

**$X\text{-ray} = r_y = dz = 0$**

**Loading: seism ac\_s2\_c\_1 [Figure 1.3-a], in axis OY applied to the two supports (factor of amplification of the signal = 137).**

**NB: the transverse reinforcements are not taken into account in calculations**

### **Reference solution**

#### **2.1**

##### **Method of calculation used for the reference solution**

*The reference solution is obtained by:*

- *software SYSPIPE of FRAMATOME,*
- *Code\_Aster: test of nonregression based on an equivalent command set.*

#### **2.2**

##### **Results of reference**

*The line of piping was the subject of a complete lawful study. Results of the analysis seismic are mentioned in the note of the manufacturer [bib1].*

#### **2.3**

##### **Uncertainty on the solution**

*Numerical solution, obtained with identical data and comparable elements.*

#### **2.4 References**

##### **bibliographical**

**Summary of the results**

**The answers obtained with the two codes are very close. Variations surplus not 1% on primary and secondary components. More important differences are observed in elbows. The latter are modelled with a curved element in SYSPIPE and 4 elements POU\_C\_T in Code\_Aster.**

multifibre beams***

## **Summary:**

***This test relates to the validation of option MASS\_INER, as well as calculation of the clean modes of the frame***

***when the model contains POU\_D\_TGM (multifibre beams). The results of the reference solution are obtained by making the same study but with a model of beams based on POU\_D\_E.***

***This test makes it possible to validate, by making a modal analysis of the structure:***

- linear finite elements of type POU\_D\_TGM.***
- results of the orders: POST\_ELEM, NORM\_MODE, EXTR\_MODE.***
- results of MACRO\_MODE\_MECA.***

### ***3 Modeling***

#### ***With***

#### ***3.1***

##### ***Characteristics of modeling and the grid***

***The model is composed of POU\_D\_TGM (multifibre beams). All the sections, are in form of "I" and are described with 30 fibres: 1 in the sole and web thickness, 10 in the width of soles and 10 in the height of the heart.***

#### ***3.2 Functionalities***

##### ***tested***

***The case test comprises three stages:***

- the first calculates the structural features with the order post\_elem,***
- the second stage consists in calculating the clean modes of the structures using orders calc\_matr\_elem, nume\_ddl, asse\_matrice, mode\_iter\_simult and with to normalize with the result of the concept post\_elem,***
- the third stage calculates the clean modes of the structure with the macro-order MACRO\_MODE\_MECA by normalizing the modes with the result of concept POST\_ELEM.***

#### ***Orders***

***AFFE\_CARA\_ELEM BEAM***

***AFFE\_FIBRE***  
***POST\_ELEM MASS\_INER***

*For the NUME\_MODE 4, the frequency is correct, on the other hand there is a relative error of 59% on MASS\_EFFE\_UN\_DX (1.9E-03 to be compared with 7.7E-04), and an absolute error of 1.1E-03. The value of*

*MASS\_EFFE\_UN\_DX indicates a weak participation of this mode to the dynamic response of structure. The two analyses are thus in agreement, there is well a mode in the vicinity of 17.5Hz, and its contribution is very weak with respect to the dynamic response of the structure.*

*After analysis of the results, calculated mode with 34.9Hz (NUME\_MODE 8 for model POU\_D\_TGM) corresponds to the mode of reference to 35.3Hz (NUME\_MODE 13). On the other hand there is a relative error*

*from 28% on the MASS\_EFFE\_UN\_DX (2.3E-03 to be compared with 1.7E-03) and an absolute error of 6.4E-04.*

*The value of MASS\_EFFE\_UN\_DX indicates a weak participation of this mode to the dynamic response structure, the two analyses are thus in agreement.*

*After analysis of the results, calculated mode with 37.6Hz (NUME\_MODE 9 for model POU\_D\_TGM) corresponds to the mode of reference to 37.0Hz (NUME\_MODE 14). On the other hand there is a relative error*

*from 30% on the MASS\_EFFE\_UN\_DX (1.7E-02 to be compared with 1.2E-02) and an absolute error of 5.1E-03.*

*The value of MASS\_EFFE\_UN\_DX indicates a weak participation of this mode to the dynamic response structure, the two analyses are thus in agreement.*

*Mode, of the reference solution, which corresponds to the frequency of 33.6Hz (NUME\_MODE 10) is not*

not found by modeling in POU\_D\_TGM. The MASS\_EFFE\_UN\_DY, corresponding to this mode is of 6.37E-04, lower than 0.1%. This value indicates a weak participation of this mode to dynamic response of the structure. The fact that one does not find this mode, with a modeling POU\_D\_TGM, thus will not influence the dynamic analysis which one could make thereafter.

### **Summary of the results**

The results of reference are obtained with a model of POU\_D\_E.

The analyses carried out with a modeling in POU\_D\_TGM are in agreement with the solution of reference.

*ld*

*&*

*U 0*

*L*

*L*

*L*

*+*

*+*

*=,*

*MR. T*

*M U*

*T*

*T*

*& D*

*& C*

*C U*

*&d K*

*K U*

*F*

*ld*

*dd*

*ld*

*dd*

*ld*  
*dd D*  
*D*

*with index L: ddl free*  
*index D: ddl imposed*

*F (T*  
*D*  
*) external loadings applied to the nodes ends and leading to displacements*  
*imposed ud is unknown, one thus eliminates these equations and one obtains:*

$$[M] \{u\dot{\ } + [C] \{u\dot{\ } + [K] \{U\} = - [M] \{u\dot{\ } - [C] \{u\dot{\ } - [K] \{U$$

*ll*  
*L*  
*ll*  
*L*  
*ll*  
*L*  
*ld*  
*D*  
*ld*  
*D*  
*ld*  
*D*).

*The only nonnull terms of the second member of this system are related to the variables kinematics relating to the node end where displacement is imposed. However, with  $t=0$ ,  $udC$*

*&*  
*and  $u\dot{d}C$  is not*  
*defined but in  $t=0^-$  and  $t=0^+$ ,  $udC$*

*&*  
*and  $u\dot{d}C$  is null. All the complexity of the problem comes from that.*

*To obtain a reference solution, we considered  $udC$*

*&*  
*and  $u\dot{d}C$  uniformly null it*  
*who amounts not considering that the forces intern elastic at the end C. This is debatable of one physical point of view but, by adopting the same assumptions at the time of the modeling of the problem,*  
*the validation of Code\_Aster can be concluded.*

*One calculates the reference solution by dealing with the following problem:*

$$[M] \{\ddot{u}\} + [C] \{\dot{u}\} + [K] \{u\} = [-K] \{U\} \quad (D, T)$$

*with  $\{u(0)\} = 0$  and  $\{\dot{u}(0)\} = 0$ .*

*With this intention, one transports the problem in the modal base of the system which checks:*

$$[M] \{\ddot{u}\} + [K] \{u\} = 0$$

*Damping being diagonal, the diagonal system is obtained:*

$$[M] \{\ddot{X}\} + [c] \{\dot{X}\} + [k] \{X\} = \{G(T)\} \text{ where } \{G(T)\} = \{G\} \text{ for } T > 0,$$

*with  $\{X(0)\} = 0$  and  $\{\dot{X}(0)\} = 0$ .*

*In modal space, one thus solves three equations (3 ddfs free) differential of the second order then one returns in physical space. One obtains then the displacement of the point medium:*

$$U(T) = \sum_{i=1}^3 e^{-\gamma_i T} \left( A_i \cos(\omega_i T) + B_i \sin(\omega_i T) \right)$$

*with  $\omega_i$ :  $i$ -ème own pseudo-pulsation of the deadened system.*

## 5 *Summary of the results*

*The results are rather close to the reference solution (numerical). (variation < 5%), for which certain data missed and thus had to be estimated. They correspond on the other hand very well with the results of the code STONE of the IAT (given identical to those of Code\_Aster).*

*This makes it possible to validate the taking into account of the offsetting of the center of torsion in the matrices of mass and of rigidity.*

**2**

**Reference solutions**

**2.1**

**Method of calculation used for the reference solutions**

**2.1.1 Loading distributed of traction and compression**

**A right beam length L working only in traction and compression is subjected to one loading distributed constant according to X but varying in a sinusoidal way according to time. It is embedded at its two ends.**

**2u**

**2**

**U**

**S**

**- E S**

**= F (T)**

)  
*t*<sup>2</sup>  
*x*<sup>2</sup>  
*U* (0

) = 0, *U* (*L*) = 0.

To solve, one applies to the equation the transform of Fourier in time:

$2 U$

=  
 $2$   
 $1$   
 $4$   
 $2$   
-  
*U* +

*F*  
( )  
 $2$   
*X*  
*E*  
*E S*

*U*: transform of Fourier of *U*,

*F*: transform of Fourier of *F*.

Thus, we have for  $F (T) = F \cos (2 T$

*O*):

$2 O$   
*sin*  
*X*  
 $2$

***SDLL403 - Vibrations of a pendulum in rotation***

***Summary***

***The applicability of this test is the modal analysis of the structures. The studied structure is a pendulum in rotation around an axis fixed and plunged in a field of gravity. The pendulum itself is articulated around one center perpendicular to the axis of rotation and located at a certain distance from this one. One is interested in the first six Eigen frequencies.***

***The interest of this test lies in the following aspects:***

- analyze modal with taking into account of initial constraints (geometrical stiffness)***
- analyze modal with taking into account of the centrifugal stiffening***
- important relative difference between two successive frequencies of the spectrum***

***Currently, the taking into account of the centrifugal stiffening is not possible that with voluminal elements.***

***The element used is element HEXA20 and one employs the method of Sorensen for the calculation of the frequencies clean.***

***The first Eigen frequency is compared with an analytical reference. The following frequencies are compared with numerical values obtained by a software independent of Code\_Aster and using modelings “beam” and “plane constraint”.***

**Reference solution**

2.1

**Method of calculation used for the reference solution**

.

*first Eigen frequency*

*The facts of the case are selected in such a way that the stiffnesses in inflection and in extension are large with respect to the stiffnesses geometrical and centrifugal. Under these conditions, the value of the first Eigen frequency is obtained analytically by considering a pendulum rigid.*

*While taking as degree of freedom the angle enters the pendulum and axis X the equation of movement is written:*

2 &

= 3

2

L

$G \cos - (3a + 2L \cos) \sin$

*One considers here the small oscillations of the pendulum around a position of balance statics 0. By linearizing the equation of the movement in the vicinity of this position, one obtains the equation with the small disturbances:*

2L &

$$\begin{aligned}
&+ [3 \\
&2 \\
&G \sin + (3a \cos + 2L \cos^2 \\
&0 \\
&0 \\
&)] = 0 \\
&0
\end{aligned}$$

*One deduces the pulsation from it from the first mode:*

$$\begin{aligned}
&3g \\
&3a \\
&2 \\
&= \\
&\sin + \\
&\cos + \cos \\
&2 \\
&2 \\
&0 \\
&L \\
&2 \\
&0 \\
&0 \\
&L
\end{aligned}$$

*This own pulsation can be still written in the form*

$$\begin{aligned}
&K () + K (2 \\
&) \\
&= \\
&I
\end{aligned}$$

*with*

$$K () I$$

.  
*other Eigen frequencies*

*The values of reference of frequencies 2 to 6 are obtained numerically by means of version 7 of software the SAMCEF software. Two different modelings were used: 20 elements of deformable beam with the shearing action and 20X4 elements of membrane with 8 nodes. results obtained in both cases are identical if one limits oneself to the first 4 digits significant. Considering the corrections of stiffness are small with respect to the terms of stiffness linear, one can check that frequencies 2 to 6 differ little from the analytical values obtained for a nondeformable beam hurled with the sharp effort. In fact, the maximum variation between the numerical and analytical values 1% do not exceed.*

**Summary of the results**

*Good agreement with the reference solution (less than 1. % of error on all the modes safe on first where the error is 2.2%).*

*This test could not be carried out with an element of beam because the calculation of the centrifugal matrix of rigidity is not available for this type of element. In the same way, as it is not available for discrete elements, we could not use connection 3D-beam. In order to stage this problem, all the nodes of surface containing point A were bound by a solid connection.*

**SDLS01 - Thin, free or embedded square plate  
at the edge**

**Summary:**

*The applicability of this case test relates to the dynamics of the structures, and more particularly modal calculation and the harmonic calculation of answer.*

*For modal calculation, it is a question of calculating the clean modes of inflection of a thin square plate in*

*two configurations:*

- Plaque embedded on an edge,*
- Free Plaque.*

*The plate is with a grid in triangular elements to which elements DKT are affected.*

*Four different modelings are tested:*

- Modal Calcul Edges of the plate directed according to axes' of the reference mark,*
- Modal Calcul unspecified Orientation of the plate and harmonic response for the plate embedded,*
- Modal Calcul by traditional and cyclic dynamic sousstructuration,*

· *Modal Calcul following a condensation of Guyan.*

*The results of reference of modal calculations result from analytical calculations. They validate on the one hand*

*tools for creation of the matrices of mass and rigidity, as well as the operators of traditional and cyclic dynamic under-structuring implemented in Code\_Aster. In addition, it case test validates modal calculation following a condensation of Guyan (condensation of the matrix of mass).*

## **7 Modeling**

**C**

### **7.1**

#### **Characteristics of modeling C**

**G**

In the 2 cases, the plate is cut out in 4 parts of equal size. Each sousstructure considered is with a grid in triangles to which elements of plate DKT are affected.

#### **Case 1: Plate embedded on an edge**

The structure is studied using the method of sousstructuration traditional with interfaces of the type CRAIG\_BAMPTON. The modal base used for each sousstructure is made up of 25 modes clean and of the constrained modes associated the interfaces.

#### **Case 2: Free plate**

The structure is studied using the method of sousstructuration cyclic with interfaces of the type HARMONIC CRAIG\_BAMPTON and taking into account of the specificity of the node of the axis (not G).

base modal used for the basic sector is made up of 25 clean modes and the modes harmonics associated with the interfaces.

## 10.2 Remarks

One seeks to calculate the first 3 nonnull Eigen frequencies of the problem of the free plate on its edges.

If one condenses the matrices on the only nodes:

(A, B, C, D, G, H, I, J, K)

The precision of the frequencies is not whereas 2%.

To obtain the results wanted with the awaited precision (1%), it is necessary to add the points (L, M, NR, O).

**11**

## Summary of the results

· Modélisations A and b:

Precision on the Eigen frequencies  $\approx$  1% until the sixth mode of inflection.

· Modélisation C:

In sousstructuration, the quality of the results could be improved by the use of a grid of finer sousstructure.

· Modélisation D:

To obtain an accuracy of 1% on the Eigen frequencies, it is necessary to condense too on the 4 nodes mediums of the edges L, M, NR and O.

**SDLS02 - Plate mean rhombus embedded at the edge**

**Summary:**

This three-dimensional problem consists in seeking the frequencies of vibration of a mechanical structure composed of a parallelepipedic plate (nonrectangular), embedded on only one side. This test of mechanics of the structures corresponds to a dynamic analysis of a surface model having one linear behavior. It comprises only one modeling.

This problem makes it possible to test the element of plate DKT and the calculation of frequencies of vibration by the method of

Lanczos.

The results obtained on the first two Eigen frequencies are in concord with those of the guide VPCS.

2

#### Reference solution

##### 2.1

#### Method of calculation used for the reference solution

The formula of reference is that given in card SDLS02/89 of the guide VPCS which presents method of calculation in the following way:

The formulation of M.V. BARTON, for a plate on side, led to:

1

$E T 2$

$F$

=

2

$I =$

$I$

, , ...

2

$I$

1 2

2

has

12 (1 - 2

)

2 =

where:

$G$

( )

$I$

with, for a Poisson's ratio = 0.3 and = 30°:

= 30°

2

3.961

1

2

10.19

2

- M.V. Barton mentions the sensitivity of the result to the order of the mode and the angle.
- This reference solution applies to the thin sections such as:  $t/a < 0.1$ .
- Coefficients  $I$  were established with a limited development of an insufficient nature.

## 2.2

### Results of reference

The first two clean modes given by:

- the formula of M.V. Barton,
- the average of 5 software packages of calculation by the finite element method.

## 2.3

### Uncertainty on the solution

Semi-analytical solution < 2%.

## 2.4 References

### Summary of the results

The results given by Code\_Aster are comparable with the results given by other codes of using calculation of the formulations different for this plate in form from parallélélogramme.

### Summary:

This three-dimensional problem consists in seeking the frequencies of vibration of a mechanical structure of type

plate. Two different configurations make it possible to test the modes of vibration in the plan of the plate (behavior out of membrane) with elastic supports on two opposed edges, and the modes of vibration in inflection of a plate supported on its contour.

This test of mechanics of the structures corresponds to a dynamic analysis of a surface model having one linear behavior. It comprises two modelings (grid in triangle or quadrangle).

This problem makes it possible to test the elements of transverse membrane and flexbeam and the calculation of

frequencies of vibration by the method of Lanczos or the method of Bathe and Wilson.

### Properties of materials

The parameters characterizing the properties of material are:

$$E = 2.1 \cdot 10^{11} \text{ Pa}$$

$$\nu = 0.3$$

$$\rho = 7.800 \text{ kg/m}^3$$

## 1.3

### Boundary conditions and loadings

#### 1.3.1 Problem of inflection

The plate is in simple support on all its sides: for any point P of the edge one has:  $W = 0$ .

#### 1.3.2 Problem of membrane

For all the points of the plate, one blocks displacement in Z and the three degrees of rotation, it be-with to say:

$$W = 0. \quad X = y = Z = 0.$$

On sides AD and BC one blocks displacement in y: for  $y = 0$ . or  $y = b$  one has  $v = 0$ .

To points A, B, C, D one attaches springs of stiffness K. The axis of these springs is direction X.

y  
B  
C

With

D  
X

The numerical value of K is as follows:  $K = 25 \text{ N/m}$ .

**2****Reference solution****2.1****Method of calculation used for the reference solution****2.1.1 Problem of inflection**

The reference solution of the problem of inflection is that given in card SDLS03/89 of the guide VPCS which presents the method of calculation in the following way.

The formulation of M.V. BARTON for a rectangular plate, posed on its four sides led for the modes of inflection with:

 $I 2$  $J 2$  $E 2 T 4$  $F =$  $ij$  $2$  $has +$  $B$  $12 (1 2$  $-$  $)$ 

with:

$I =$  a number of half-length of wave according to  $y$  (dimension  $has$ ),

$J =$  a number of half-length of wave according to  $X$  (dimension  $b$ ).

**2.1.2 Problem of membrane**

The problem dealt with out of membrane is equivalent for the research of the first frequency of vibration with the following unidimensional problem:

 $2 K$  $2 K$  $m$  $X$ 

where:

$K$  is the stiffness of the springs,

$m$  is the mass of the plate.

 $4k$ 

The sought frequency is thus:  $F = 1$

 $2$  $m$ **2.2**

## Results of reference

For the problem of inflection, one calculates the first six frequencies of vibration and for calculation in membrane, one calculates only the first frequency.

### 2.3

#### Uncertainty on the solution

The solutions being analytical, there is no uncertainty.

## 3 Modeling

### With

#### 3.1

#### Characteristics of modeling

One cut out the plate in 200 meshes TRIA3. Two modelings for the plate are used: DKT and DST.

For the problem of inflection, the boundary conditions are as follows:

· in all the nodes of the edge:  $DZ = 0$

For the problem of membrane, the boundary conditions are:

· in all the nodes of the grid:  $DZ = 0$   $DRX = DRY = DRZ = 0$ ,

· in all the nodes on the sides AB and BC:  $DY = 0$

· at the points A, B, C, D one adds discrete elements of rigidity (direction X).

**Summary of the results**

The precision, for the modes of inflection, remains acceptable on the first six modes. Let us note however that the precision is worse than in the case of the free plate in space (test SDLS01 [V2.03.001]).

It is noticed that the treatment of the modes of solid body is suitable.

For the test out of membrane, the results are very satisfactory.

**SDLS04 - Under-structuring cyclic:**

**Annular thin section embedded in its hub**

**Summary:**

The applicability of this test relates to the dynamics of the structures, and more particularly calculation

modal by cyclic dynamic under-structuring.

It is a question of calculating the clean modes of an axisymmetric structure (annular thin section embedded in sound

hub) by regarding it as a structure with cyclic repetitivity.

The model consists of an angular sector of  $20^\circ$  of the ring, with a grid in triangles to which are affected elements of the type plates: DKT. Two methods of calculation are tested:

- cyclic dynamic Under-structuring of Craig-Bampton
- cyclic dynamic Under-structuring of Mac Neal

The results of reference result from an analytical calculation. They validate the modal computational tools by

cyclic dynamic under-structuring implemented in Code\_Aster.

## 5 Modeling

### B

#### 5.1

##### Characteristics of modeling

This structure with cyclic repetitivity is studied using the method of under-structuring cyclic dynamics of MAC-NEAL.

A basic sector, consisted an angular sector of 20°, is with a grid in triangles to which are affected elements of plate DKT.

The modal base used for the sector is made up of 20 clean modes and the **modes of fastener** associated the interfaces.

#### 5.2

##### Characteristics of the grid

A number of nodes: 66.

A number of meshes and types: 100 triangles with 3 nodes DKT

#### 5.3 Functionalities

**SDLS07 - Clean modes of an envelope  
spherical thin**

**Summary:**

This test from guide VPCS makes it possible to validate the algorithm of search for eigenvalues `MODE_ITER_SIMULT` [U4.52.02] with the operators of rigidity and mass corresponding to modelings following:

1) Three-dimensional hulls: finite elements DKT (maillage of one 1/8 of sphere),

2) Elements

finished

2D axisymmetric TRIA6 and QUAD8 (grid of a section),

3) Three-dimensional hulls: axisymmetric finite elements isoparametric SEG3 (linear grid of the section),

4) Hulls

three-dimensional

COQUE\_3D: finite element MEC3QU9H (grid 1/8 of sphere),

5) Hulls

three-dimensional

COQUE\_3D: finite element MEC3TR7H.

The results obtained are compared with the analytical solution (HAYEK) and reveal for the six first modes of the lower deviations than:

- 0,45% for the axisymmetric elements continuous mediums,
- 0,20% for the elements of hull DKT,
- 0,17% for the elements of axisymmetric hulls isoparametric,
- 0,17% for elements COQUE\_3D.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

For the thin spheres ( $i.t \ll R$  with  $I$ , order of the mode), the clean modes with displacement radial and tangential establish by a theory of membrane are given by [bib1] and [bib2]:

$E$

$F$

$I$

=

$I$

$2 R$

$(1-2)$

$= 1 B \pm b^2 - 4 1-2$

$2 + - 2$

$= 2$

with

and

$+ +1+$

$I$

(

)  $(I I) B I I 3$

$2$

The theory presented by Hayek makes it possible to introduce a correction of the effect of inflection (approximation of

general theory of Wilkinson) who leads to values of  $I$  function of

$= T 2 has/$

$R^2$

$12$

$B = I (I +)$

$1$

and solution of:

$4$

$2$

$2$

$2$

$2$

#### **4.2 Remarks**

The reference solution does not give the multiplicity of the modes. One observes with calculations of orders of multiplicity which grow with the value of the frequency.  
Modes 3, 5, 7, 9 are not obtained because of the boundary conditions chosen for this model, with the three symmetry planes.

## Summary of the results

- Modeling hull DKT, here restricted with the modes having 3 symmetries compared to plans  $X = 0$ ,  $y = 0$ ,  $Z = 0$ , provide the Eigen frequencies with an error lower than 0.4% on the 20 first modes.
- Modeling continuous medium axisymmetric 2D provides the Eigen frequencies with an error lower than 2%.

- Modeling COQUE\_AXIS (quadratic isoparametric elements) provides the frequencies clean with an error lower than 0.2% on the first 5 modes (space discretization identical to the trace of the axisymmetric grid 2D).
- Degenerated modeling COQUE\_3D (elements of thick hull MEC3QU9H, MEC3TR7H) to provide the Eigen frequencies with an error lower than 1.2% on the first 10 modes.

**SDLS100 - Study of grids on a plate**

**square thin**

**Summary:**

This three-dimensional problem consists in seeking the frequencies of vibration of a mechanical structure composed of a thin square plate embedded on a side. One studies the influence of the distortion of the grid

on the results. This test of Mechanics of the Structures corresponds to a dynamic analysis of a model surface having a linear behavior. It comprises three modelings.

This problem makes it possible to test the element of plate DKT in transverse inflection and the calculation of the frequencies

clean, either by the method of Lanczos, or by the method of Bathe and Wilson. The first modeling consist in netting finely and regularly the plate by triangles. For the second modeling, it grid is coarser while for the third, it coarse and is distorted.

The first modeling is used as results of reference.

The results obtained are in concord between them and with those of a card NAFEMS. The effect of distortion of

grid does not appear on the first frequencies of vibration.

## **Reference solution**

### **2.1**

#### **Method of calculation used for the reference solution**

The reference solution is that given in the card "Test 16" of the tests of reference published by NAFEMS.

Card NAFEMS gives the results of reference as well as computation results carried out in using elements of the mean hull type of Kirchoff based on a formulation of displacement isoparametric quadratic (ddl of rotation and normal translation to the plate).

- For tests 1 and 2, the quadrangles of card NAFEMS were cut out in triangles.
- Tests 3 and 4 can be carried out by Aster (not quadratic element of hull).
- Until the 9th mode, the error on the frequency is  $\approx 2.5\%$ .
- The effect of distortion of the grid appears really only on modes 7 and 12.

**SDLS101 - Thin rectangular plate on mattress  
rubber band**

**Summary:**

This test makes it possible to validate modeling "APPUI\_REP" [U4.22.01] for elements of hull. It corresponds

with calculations of frequency of inflection of a thin rectangular plate which rests on an elastic mattress.

By

report/ratio with test SDLS03 [V2.03.003], which validates the frequencies of vibrations of a plate pressed on its edge,

this test validates modeling "APPUI\_REP" and order CREA\_MAILLAGE [U4.12.06]. The plate is with a grid with triangles and quadrangles.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

The formulation for a rectangular plate thickness  $T$  posed on the four sides leads to:

$I_2$

$J_2$

And 2

$F =$

$ij$

2

has +

$B$

12 (1-2)

with:

$I =$  a number of half-lengths of wave according to  $y$

$J =$  a number of half-lengths of wave according to  $X$

The formulation for the plate posed on the four sides and resting on a led elastic mattress with:

$$F = \frac{E}{12} \left( \frac{1}{I^2} + \frac{1}{J^2} \right) T$$

with  $E$ : density of stiffness per unit of area.

compression**

### **Summary:**

This test makes it possible to validate the calculation of the Eigen frequencies of a paddle of compression by using the order

MODE\_ITER\_INV [U4.52.01].

Modelings correspond to the use of elements “COQUE\_3D” MEC3QU9H (modeling A) and MEC3TR7H (modeling B).

The reference solutions are experimental results. The variation enters the numerical results and them experimental values does not exceed 4,5% for two modelings.

***Problem of reference***

***1.1 Geometry***

*The studied configuration consists of two 4 meters height coaxial cylindrical hulls:*

*2m  
4m  
0.1m*

*The internal hull has an average radius of 1 meter and a thickness of 1 centimetre.*

*The external hull has an average radius of 1,10 meter and a thickness of 1 centimetre.*

## *1.2 Properties*

*material*

*The material constituting the two hulls is steel. Its physical characteristics are:*

*= 7800 kg/m<sup>3</sup>  
E = 2. 10<sup>11</sup> Pa  
= 0,3*

## *1.3*

*Boundary conditions and loadings*

*The conditions of self-supporting quality are the same ones for the two hulls: partly embedded ends lower (Z = 0) and free partly higher (Z = 4 m).*

### **Reference solution**

**2.1**

#### **Method of calculation used for the reference solution**

*The reference solution is provided by a calculation carried out by means of Code\_Aster implementing operator CALC\_MATR\_AJOU.*

*With this intention, one uses a grid on which the elements of the structure (hulls internal are defined and external), voluminal elements of fluid (annular space) and elements of interface fluid-structure. This method is described completely in [bib1].*

*On the elements of interface, the condition normal speed limit null is imposed, translating condition of nonpenetration of the fluid in the hulls.*

*On the sections of entry and exit of annular space, the limiting condition of null potential is imposed, translating the condition of null disturbed pressure at the ends.*

*One carries out the first modal calculation of the structure in air. Operator CALC\_MATR\_AJOU allows*

*then to calculate the matrix of mass added by the fluid, projected on the basis of modal structure in air. One can then recombine this matrix of mass added with the matrix of mass generalized of the structure in air, then to solve a new modal problem which leads to characteristics of the water system at rest. Results obtained for the Eigen frequencies system out of water at rest constitute the reference solution.*

*Characteristics of the grid 17 nodes on a vertical generator*

*:*

*60 nodes on a crown*

*960 meshes QUAD4 on each hull*

*=> 1920 meshes for the interface fluid-structure*

*2880 meshes HEXA8 for the fluid field*

*180 meshes QUAD4 for the section of entry of annular space*

## ***180 meshes QUAD4 for the section of exit of annular space***

### ***2.3***

#### ***Uncertainty on the solution***

***In the studied case, the half-thicknesses of hull account for 10% of the dimension of the annular play. In the calculation of reference realized by operator CALC\_MATR\_AJOU, the half-thicknesses are neglected for the definition of the fluid field. One thus awaits a systematic error about 5% on the frequencies, because of this approximation.***

***Moreover, differences of modeling and resolution between the numerical method implemented in operator CALC\_MATR\_AJOU and the analytical model developed in the operator CALC\_FLUI\_STRU induce an additional variation.***

### **3 Modeling**

**With**

#### **3.1**

##### **Characteristics of modeling**

*The geometry of the structures and the characteristics of material constituting the hulls were presented before.*

*Concerning the absolute roughness of wall of the structures, one takes a value of 105 meter.*

*The surrounding fluid is water. Values taken for the density and viscosity kinematics are respectively*

*= 106 m<sup>2</sup>/s.*

*F = 1000 kg/m<sup>3</sup> and*

*F*

*One considers the flow not confined upstream and downstream from the structures.*

*The problem of coupling fluid-structure is solved by analytical model MOCCA\_COQUE [bib2] integrated in Code\_Aster (operator CALC\_FLUI\_STRU), for a mean velocity of flow null: one thus obtains the modal characteristics of the water system at rest, by catch in count effects of added mass.*

#### **3.2 Characteristics**

**grid**

*Compared to the calculation of reference, the characteristics of the grid are similar, with the difference*

*close the fluid field is not represented any more. In order to make the two hulls interdependent one of the other, one adds a group of meshes connecting the nodes to the level of embedding.*

*One a: 17 nodes on a vertical generator,*

**60 nodes on a crown,**

**960 meshes QUAD4 on each hull,**

**60 meshes QUAD4 to solidarize the two hulls (bases embedded).**

### **3.3**

#### **Stages of calculation**

**The definition of the characteristics of a hardware configuration made up of two hulls cylindrical coaxial for a calculation of coupling fluid-structure is given via operator `DEFI_FLUI_STRU` key word factor `COQUE_COAX`.**

**The resolution of the coupling fluid-structure for a configuration of the type “coaxial hulls” and its calculation of the modal parameters (reduced frequencies and depreciation) and deformed modal out of water at rest are realized with operator `CALC_FLUI_STRU`.**

***4.2 Remarks***

*The results are in conformity so that one could wait. One observes indeed:*

- a systematic error of about 5%, because of not taken into account thicknesses of hull for the definition of the fluid field in the calculation of reference;*
- a residual variation due to the differences of modeling and resolution between the two operators CALC\_MATR\_AJOU and CALC\_FLUI\_STRU.*

*Modes 1 to 6 are modes for which the structure is strongly coupled with the fluid. In practical, these modes correspond to movements of the hulls internal and external overall in opposition of phase. For these modes, the terms of added mass are theoretically proportional*

*3*

*F*

*R*

*with*

*, where R indicates the average radius and H the thickness of annular space.*

*H*

*For these the first six modes, the results provided by CALC\_FLUI\_STRU lead to frequencies clean lower than those calculated by CALC\_MATR\_AJOU. Indeed, H being weaker, them terms of added mass are larger.*

*Modes 7 to 12 are modes for which the structure is slightly coupled with the fluid. In practical, these modes correspond to movements of the hulls internal and external almost in phase. Thus, the terms of added mass are theoretically proportional to the water mass involved, i.e. with*

*F*

*RH.*

*In this case, it is normal that the results provided by CALC\_FLUI\_STRU lead to Eigen frequencies higher than those calculated by CALC\_MATR\_AJOU. Indeed, H being more weak, the terms of added mass are smaller.*

**SDLS108 - Use of option RIGI\_PARASOL  
within the framework of a study EPR**

**Summary:**

**The goal of the test is to test the option RIGI\_PARASOL which makes it possible to distribute stiffnesses of floor under a foundation raft of building. This option is called successively in orders AFFE\_CARA\_ELEM and CALC\_AMOR\_MODAL.**

**In order AFFE\_CARA\_ELEM, it makes it possible to calculate then to affect by a modeling DIS\_TR them specific stiffnesses of a carpet of springs of floor under the foundation raft of building. In the order CALC\_AMOR\_MODAL, these values make it possible to calculate modal potential energy in the ground which contributes with the calculation of modal depreciation according to the rule of the RCC-G [bib1].**

**The studied case is an industrial structure of the nuclear small island of EPR. It includes/understands only one modeling. It**

*case test is thus used to test nonthe regression of the code as much as it constitutes documentation on its use in oneself. The model of approximately 40000 degrees of freedom consists of 6700 nodes and 10300 elements approximately: 9500 elements DKT, 100 elements of beam and 700 discrete elements of connection.*

*This industrial case-test is representative of the studies led by SEPTEN/MS on modelings 3D of civil engineering subjected to the seism and makes it possible to reabsorb the tools used within this framework. The comparison relates to frequencies and depreciation for the first modes calculated on carpet of springs of ground. The values of reference for a ground of the type SA (soft ground) are given in note E.N.T.MS 96.052 A*

*[bib2].*

*The 6 values of total stiffnesses of ground to be distributed under the foundation raft are determined by PARASOL for modulate ground of the type SA (444 MPa).*

## **2** **Reference solution**

### **2.1** **Method of calculation used for the reference solution**

*The modal damping coefficients are calculated according to the rule of the RCC-G [bib1]. They are obtained by summoning depreciation of the substructures constitutive of a building and them depreciation structural and geometrical of the ground balanced by their respective rates of energy potential compared to total potential energy, and that for each mode. There are 2 methods and two key words of CALC\_AMOR\_MODAL to estimate the contribution of the ground with the potential energy according to that one average modal efforts (key word "RIGI\_PARASOL") or modal displacements (key word "DEPL") with the nodes of the foundation raft.*

### **2.2** **Results of reference**

*The results of reference, frequencies, masses effective and modal depreciation are provided in the note bench-mark datum [bib2]. They were calculated by Code\_Aster. It should be noted that modal depreciation was also calculated by affecting a stiffness to each node of the foundation raft (instead of RIGI\_PARASOL).*

### **2.3** **Uncertainty on the solution**

*Results of the industrial study. The case-test is thus included/understood like a test of not-regression of code.*

**Summary of the results**

*Results of the depreciation obtained by CALC\_AMOR\_MODAL with the method of the forces (key word "RIGI\_PARASOL") with or without truncation of threshold to 30% are exactly the same ones as those given in the reference [bib2]. They are very close to those obtained by CALC\_AMOR\_MODAL with the method of displacements (key word "DEPL"), also identical to those given in reference [bib2].*

***Handbook of Validation  
V2.03 booklet: Linear dynamics of the hulls and plates  
Document: V2.03.109***

***SDLS109 - Eigen frequencies of a ring  
cylindrical thick***

***Summary:***

***This test is inspired by a vibratory study carried out on collector VVP of the N4 sections. This collector is thick and a maximum report/ratio thickness presents on average radius of 0,13. This value, being able to be typical of an industrial structure, is slightly higher than the limiting value of usually recognized validity for the plates and hulls. In this study, the modeling of the collector in hulls is then evaluated by comparison with a voluminal model on a ring.***

***This test makes it possible to evaluate the algorithm of search for eigenvalues MODE\_ITER\_SIMULT [U4.52.03] with operators of rigidity and mass corresponding to following modelings:***

- 1) plates of the type DKQ (finite element MEDKQU4) and DSQ (finite element MEDSQU4),***
- 2) plates of the type DKT (finite element MEDKTR3) and DST (finite element MEDSTR3) with an ear grid and in star grid,***
- 3) three-dimensional hulls of type COQUE\_3D (finite elements MEC3QU9H and MEC3TR7H),***

**4) sections of hull in plane constraints of type COQUE\_C\_PLAN (finite element METCSE3),  
5) telegraphic elements with kinematics of beam and modes of Fourier PIPE (finite element METUSEG3) and  
TUYAU\_6M (finite element MET6SEG3).**

**The results obtained are compared with the solution resulting from a voluminal modeling of the ring (element finished MECA\_HEXA8) revealing the modes of Fourier of order 2 (ovalization) and 3 (trifoliolate) like 2 modes except plan. The variations on the frequencies of the modes of ovalization and trifoliolate are close to:**

**.  
0.4% in DSQ and COQUE\_3D in QUAD9,  
.  
0.7% in COQUE\_3D in TRIA7, COQUE\_C\_PLAN, PIPE and TUYAU\_6M,  
.  
1% for the DKQ, DKT and DST.**

**1  
Problem of reference**

**1.1 Geometry**

**Rm  
L**

**T**

*It is of a cylindrical ring, average radius  $R_m = 0.369$  m, about thickness  $T = 0.048$  m and of length  $L = 0.05$  Mr.*

**1.2**

***Properties of material***

*The material is homogeneous, isotropic, elastic linear. The elastic coefficients are:  
 $E = 185.000$  MPa and  $\nu = 0.3$ .*

*The density is constant and is worth:  $\rho = 7800$  kg.m<sup>3</sup>.*

**1.3**

***Boundary conditions and loadings***

*The structure is free in space.*

**1.4**

***Order of magnitude of the Eigen frequencies***

*The required clean modes correspond to the modes of Fourier of order 2 and 3 of the ring. frequencies of a ring can be estimated starting from an analytical model of curved beam of Euler [bib1]. For a mode of Fourier of order N, the frequency is worth:*

$$N(N^2 -$$

1

 $E I$  $F$  $y$ 

=

 $N$ 

2

 $R^2$ 

2

 $m$  $m(N +)$ 

1

 $Lt^3$ 

where:  $I =$

=

 $y$ 

and  $m$

*Lt*  
*12*

*For the modes of ovalization ( $N = 2$ ) and trifoliate ( $N = 3$ ), the corresponding frequencies are worth respectively 211.65 Hz and 598.64 Hz. The search for clean modes is carried out on the tape 200 - 800 Hz in order to collect these 2 modes of Fourier.*

## **5.2 Remarks**

*Modelings in plates DKQ and DSQ do not make it possible to represent the modes correctly except plan. One can think that that is due to the number of meshes over the too low length (4 with the place from 8 in the modeling of reference). The first frequency except plan in plates DSQ must be lower than 200 Hz.*

### **Summary of the results**

.  
*Even if the results obtained are honourable, models DKQ, DSQ, DKT, DST, COQUE\_C\_PLAN, PIPE and TUYAU\_6M do not make it possible to estimate the modes except plan of the ring. Only model COQUE\_3D with a grid in QUAD9 provides a good estimate frequential of these modes with an error lower than 0.4%.*

.  
*Models DSQ and COQUE\_3D in QUAD9 give an error close to 0.3% for the modes of ovalization and trifoliate. For models COQUE\_3D in TRIA7, COQUE\_C\_PLAN, PIPE and TUYAU\_6M, this error border 0.7% and are higher than 1% for the DKQ, DKT and DST.*

.  
*The best results of the DSQ compared to the DKQ confirm than the effect of shearing transverse is not negligible in the hulls notable thickness.*

.  
*On a developable geometry like that of the cylinder studied here, finite elements quadrangular provide better results which triangular finite elements. DST, tested on an ear grid and a symmetrical star grid, are much less goods than DSQ. The same remark is also valid for the COQUE\_3D in TRIA7 by report/ratio with the COQUE\_3D in QUAD9.*

.  
*The performances of the COQUE\_3D are good quantitatively and in computing times. richness of the interpolation, the taking into account of the curve of the cylinder in the elements and metric correction carried out in the thickness of the hull seem to explain these good results.*

.  
*Elements SHB8 make it possible to about obtain all the modes with a maximum change 1%.*

***SDLS114 Calculation of the factors of intensity of  
constraint of a plate fissured by recombination  
modal***

***Summary***

*This test aims at validating the calculation of the factors of intensity of a plate fissured by modal recombination.*

*modal factors of intensity, i.e associated each clean mode of vibration of the structure, are calculated with*

*operators CALC\_G\_THETA\_T (option K\_G\_MODAL) in 2D and CALC\_G\_LOCAL\_T (option K\_G\_MODAL) in 3D.*

*This test contains a modeling 2D and a modeling 3D. The reference solution results from one direct temporal resolution of the transitory problem.*

*Two modelings illustrate the possibility of recombining the modal factors of intensity directly in the command file by instructions python.*

*Problem of reference*

*1.1 Geometry*

*One considers a plate height  $H = 0,1$  m, dispatcher  $L = 0,05$  m and thickness  $E = 0.005$  Mr. Une crack is positioned in the middle of the height of the beam, with a depth of  $0,1$  L.*

*F*

*y*

*X*

Z

## 1.2

### **Material properties**

*One considers the traditional properties of a steel:*

*Young modulus:*

$$E = 2.10+5 \text{ MPa}$$

*Poisson's ratio:*

$$= 0.3$$

*Density*

$$= 7800 \text{ kg/m}^3$$

## 1.3

### **Boundary conditions and loadings**

*The plate is:*

- *embedded on S1 surface;*
- *subjected to a force  $\mathbf{F}(T)$  on S2 surface.*

*The evolution of the standard of  $\mathbf{F}(T)$  is traced on the figure above. One takes  $\Delta t = 0,001 \text{ S}$ . the direction of the force  $\mathbf{F}(T)$  is as follows:*

- *$\mathbf{F}(T) = F(T) \cdot \text{ex}$  for modeling A;*
- *$\mathbf{F}(T) = (a\text{ex} + b\text{ey} + c\text{ez}) F(T)$  for modeling B, with  $B = 2a$  and  $C = 0.4 A$ .*

*For modeling A, one blocks displacements in direction Z (plane problem).*

## **Reference solution**

**2.1**

### **Method of calculation used for the reference solution**

*The reference solution is that obtained by a direct temporal resolution of the problem transient. Operator DYNA\_TRAN\_EXPLI is used to identify the fields of displacement, with a diagram of integration in times of Newmark.*

*The evolution of the stress intensity factors according to time is then calculated by interpolation of the jumps of displacements (operator POST\_K1\_K2\_K3).*

**2.2**

### **Result of reference Modeling A**

*For modeling A, the plate is requested by a force in the plan (O, X, y) and displacements in direction Z are blocked. The result of reference, calculated by direct temporal resolution on a grid 2D, is traced on the following figure. The horizontal displacement top of the plate and its factor of intensity of the constraints oscillate with a frequency corresponding to the first clean mode structure.*

**2.3**

### **Result of reference Modeling B**

*The evolution of the three factors of intensity of the constraints is traced on the following figure for the node*

*located in the middle of the bottom of crack. The oscillations of the factors of intensity of the constraints show*

*dominating contribution of the first mode of inflection of the plate in direction X and the first mode of inflection in direction Z.*

***4.2 Notice***

***The difference between the modal values calculated by interpolation of the jumps of displacement or by method theta is weak and coherent with that observed on the static problems.***

***The value of KI (T) is calculated starting from KI modal (method K\_G\_MODA) and of the coefficients of the resolution about modal base directly in the case test by lines of order in python:***

***M***  
***K (T) = (T). I***  
***K***  
***I***

**I**  
**I**  
**I I**  
**=**

*where the coefficients (T  
I) are the coefficients of modal participation, extracted the result from  
the operator DYNA\_TRAN\_MODAL, and I  
K are the modal factors of intensity of the constraints.  
I*

*The precision obtained is satisfactory taking into account the number of elements retained in the base  
modal. The precision increases quickly with the number of modes [bib1].*

## 6.2 Notice

*The difference between the modal values calculated by interpolation of the jumps of displacement or by method theta is high: that is explained by the linear grid very little refined in the thickness of the plate.*

*The value of  $K I (T)$  is calculated starting from  $K I$  modal (method  $K\_G\_MODA$ ) and of the coefficients of the resolution about modal base directly in the case test by lines of order in python:*

**$M$**   
 **$K (S, T) = (T). I$**   
 **$K (S)$**   
 **$I$**   
 **$I$**   
 **$I$**   
 **$I I$**   
**=**

*where the coefficients ( $T$ ) are the coefficients of modal participation, extracted the result from the operator  $DYNA\_TRAN\_MODA$ , and  $I$   $K (S)$  are the modal factors of intensity of the constraints.*

*The precision obtained is satisfactory taking into account the number of elements retained in the base modal (50) and cuts it grid. The precision increases quickly with the number of modes [bib1].*

***Summary:***

*The applicability of this test is the seismic analysis. The studied structure is an air cooler subjected to an excitation ground.*

*Displacements are calculated along meridian in plan XZ.*

*The objective is to test axial, tangential and normal displacements for modal recombinations CQC and SRSS, for elements hull 3D.*

*Displacements of reference come from results obtained by several computer codes.*

*One is interested more particularly in calculation of the Eigen frequencies of this system. Values of reference are obtained on a model of Fourier with the computation software of structures the SAMCEF software.*

## ***Summary of the results***

***One is interested in two the first hundred modes of the structure: those are located in band 0 - 7Hz.***

***One finds well these frequencies with Code\_Aster with a maximum change compared to the solution of reference of 1.7%.***

***Four modes make it possible to obtain an effective mass cumulated according to X and there of 83.2%. Mass***

***effective cumulated according to Z is null. These effective weight breakdowns are identical to those obtained with the SAMCEF software.***

***For seismic calculation, displacements obtained are far away from the reference solution. However, one can express some doubts on the validity of these results of reference, being data the bad representation of the mass: indeed, for this calculation of reference, the mass effective cumulated in direction X accounts for 43% of the total mass. This is why this part of calculation was put in comment in the case-test.***

***SDLS501 - Free vibrations of a corrugated sheet***

***Summary:***

***This test represents a calculation in dynamic modal analysis of an iron corrugated into free-free. This test allows to validate modeling finite elements COQUE\_D\_PLAN. There is a test of the same structure in statics non-linear material (SSNV115) [V6.04.115].***

***The frequencies and the modes obtained are compared with a reference solution obtained with Code\_Aster starting from a modeling D\_PLAN.***

***SDLS502 - Square plate “solid” simply supported***

**Summary:**

***This test simply represents a calculation in dynamic modal analysis of a thick square plate supported. This test makes it possible to validate:***

- modelings finite elements DST, DKT, COQUE\_3D with meshes QUAD4 and TRIA3, QUAD8 and TRIA6, and 3D with meshes HEXA20,***
- the taking into account of rigidity in transverse shearing.***

***The frequencies and the modes obtained are compared with a reference solution, suggested by NAFEMS, obtained with a calculation finite elements of voluminal type.***

## **17 Summary of the results**

**Taking into account the nature of the numerical solution (voluminal finite elements), the results obtained**

**are satisfactory for:**

- modeling A and B (DST) the maximum change is less than 4% for the first 5 modes,**
- modeling E and F (COQUE\_3D), the maximum change is approximately 5% for the 5 first modes,**
- modeling G (3D), the maximum change is approximately 5% for the first 5 modes,**
- the modes of reference 5&6 except plan have symmetry different from those met in modelings E, F and G, but they are equivalent because it is about modal recombinations.**

**Modelings C and D (DKT) are less satisfactory with relative variations reaching 10% on mode 7 except plan, this due to is not taken into account of transverse shearing for this plate relatively thick.**

**Moreover one observes the appearance of modes of inflection and membrane for all these modelings, y included/understood voluminal modeling 3D G. When one refines sufficiently the grids, this tendency is confirmed and the relative variations regress. Calculation 3D in addition showed that in on this side of a grid 6x6 in plan (XY), the modes of inflection and membrane were not detected.**

## ***11 Summary of the results***

***Modeling DKT is not adapted to model this case-test, the errors are very important.***

***Formulation DKT does not take into account transverse shearing contrary to modeling***

***DST. For this type of example, where the structure makes up of a composite material and relatively thick ( $h/L = 0.1$ ), it is preferable to use DST modeling.***

***The results obtained with DST are:***

***.  
satisfactory for the first 3 frequencies with mesh TRIA3 and for the 5 first frequencies for mesh QUAD4 with a better precision for mesh QUAD4,  
.***

***the error of 10% for 4th and 5th frequency with mesh TRIA3 is significant. One finer grid should make it possible to improve the results by having the best representation of the last modes.***

***SDLV100 - Vibration of a slim beam  
of variable rectangular section (embed-free)***

***Summary:***

***The studied structure is a beam out of free steel embedded with rectangular variable section modelled by voluminal elements. One is interested in his Eigen frequencies in inflection. The same problem is dealt with in modeling beam in the case test SDLL09.***

***This problem makes it possible to test voluminal elements MECA\_HEX20 and MECA\_PENTA15 in modal analysis.***

***It also makes it possible to test option MASS\_MECA\_DIAG of calculation of the matrices of mass diagonalized for voluminal modelings.***

*The reference solution is a numerical solution obtained using the computer code by finite elements The SAMCEF software for similar modelings. The results obtained are also in concord with semi-analytical results given in guide VPCS.*

## 2

### **Reference solution**

#### 2.1

##### **Method of calculation used for the reference solution**

*The reference solution is obtained using the computation software by finite elements the SAMCEF software for*

*identical modelings but with elementary matrices of mass coherent.*

*One points out the analytical solution given in card SDLL09/89 of guide VPCS. The equation differential in inflection of the beam considered, in theory of Euler-Bernoulli is written (Theory of Euler-Bernoulli):*

## 2

2

v

*E I*

*Z*

2

*X*

2 v

= - A

2

*X*

2

*T*

*where I<sub>z</sub> and A vary with the X-coordinate.*

*The Eigen frequencies are then of the form:*

*l*

*H*

*E*

*F*

*l*

*I*

=

*I*

(,)

2

*L2*

12

*H*

*B*

*with*

=

0

= 4

*and*

=

0

= 4.

*H*  
*B*  
*1*  
*1*

*For this value of and, the first values of the continuation (I) are:*

*1*  
*2*  
*3*  
*4*  
*5*  
*= 4*  
*23.289 73.9 165.23 299.7 478.1*

## **2.2**

### ***Results of reference***

*The results of reference selected are the first 5 Eigen frequencies of the modes of inflection.*

## **2.3**

## **7 Summary of the results**

*The differences between the results of calculations Aster and the SAMCEF software with coherent masses are lower than 0.2%.*

*Differences between the computation results Aster with diagonal masses and the SAMCEF software with masses*

*coherent remain lower than 1%.*

*These results are in conformity so that one could wait, and validate in a reliable way them calculations of Eigen frequencies in Aster by MODE\_ITER\_INV and operator CALC\_MATR\_ELEM in coherent masses as in diagonal masses.*

***Reference solution***

***2.1***

***Method of calculation used for the reference solution***

***Case without fluid:***

*Let us consider the heterogeneous field described with [§1] in absence of the fluid. It is supposed that*

*the beams*

*respect the assumptions of modeling of a right beam of Euler Bernoulli. Since conditions in extreme cases applied to the whole of the beams are the same ones as for each one of them, one can bring back the research of the Eigen frequencies of the unit to that of only one beam.*

*The following problem is thus studied:*

*That is to say a beam  $B_i$  embedded [2.1-a] in the same way characteristic geometrical and material that them*

*beams of the heterogeneous medium. One notes  $A$  the surface of the section,  $L$  his length, and  $I$  the moment of inertia of inflection.*

*By the method of rigidity dynamic one shows that such a beam admits frequencies double the form:*

$$F = \frac{2 I E}{L^2} \quad (2.1-a)$$

$F =$

$I$

$I$

$2 L^2$

With

=

$I$

*$(2i + 1)/2 I = 1, 2, \dots$  for the second case of boundary conditions: [2.1-a].*

*Embedding*

$Z$

$L$

$X$

*Embedding*

**Appear 2.1-a**

*The field contains NR beams independent between them (not of boundary conditions which couples displacements of two different beams), It results from it that the multiplicity of the frequencies is equal with  $2N$  ( $2$  modes of inflections by beams).*

*For the homogenized medium discretized by the finite elements h xa dre with 8 nodes or h xa dre with 20*

*nodes, the number NR must be replaced by the number of straight lines parallel with the axis of the beams.*

**Case with fluid:**

*The case with fluid is more difficult to solve analytically: no analytical result was found until the drafting of this case test. The results of reference which one has benches thus come from one numerical resolution by finite elements of the complete heterogeneous problem. One used for this fact version 3.6.2 of Code\_Aster.*

*Each beam is represented in the grid by its average fibre modelled by POU\_D\_E (beam right-hand side of Euler). For all the beams, one binds each node of average fibre to the nodes of side surface, located in the same transverse section as the node in question, by LIAISON\_SOLIDE. The fluid interface beam is modelled by FLUI\_STRU which translates the continuity of*

*normal speeds with the walls. The fluid, was to be perfect incompressible, one deduced his modeling of that of the compressible true fluid 3D\_FLUIDE by removing the contribution of the pressure. Boundary conditions imposed on the fields [§1.3], and especially the relation which couples it displacement of all the beams on the level of HS, reveal two kinds of clean modes of the structure:*

*Modes of sets: all the beams become deformed in the same way and top surfaces it a displacement not no one admits.*

*Local modes: they correspond to modes of embed-embedded beams.*

*surfaces top thus admits a null displacement. None of these modes can correspond to an overall mode.*

*The action of the fluid results in an effect of added mass and thus a lowering of the frequencies by report/ratio with the case without fluid. It also causes, in the case of the local modes, to spread out the spectrum of associated frequencies. In the case without fluid one saw that this spectrum was concentrated in only one frequency of vibration.*

### **Summary of the results**

The results show the good modal behavior of the elements of modeling 3D\_FAISCEAU in inflection, absence of the fluid. It show also a very good agreement of the frequencies of the modes overall with calculation Aster into heterogeneous, when there is fluid.

For the frequencies of the overall modes, one does not observe differences between a grid HEXA8 and HEXA20 (this is not true for the other modes).

### ***SDLV120 - Absorption of a wave of compression in an elastic bar***

#### ***Summary***

*One tests the elastic paraxial elements of order 0 intended to apply conditions absorbing to border of a grid finite elements to simulate the infinite one in direct transitory calculations. Are used they to model an infinite elastic bar, in 3D or 2D, in which one creates a wave of pressure by imposing a displacement on the one of the ends. One is interested in nonthe reflexion of the wave in the “infinite” end of the bar.*

*One tests successively the two direct transitory operators of Code\_Aster, namely DYNA\_LINE\_TRAN and DYNA\_NON\_LINE.*

## ***1.1 Geometry***

***The system considered in the case 3D is that of an elastic bar with square section. One is imposed displacement according to X on one of the vertical faces and one observes the propagation of a wave of compression. The side surface of the bar is left free. One places the elements absorbents on face opposed to the face of excitation to simulate the infinite character of the bar in this direction. In the case 2D, the principle is identical with a very broad supposed bar which one does not model that a vertical section (see diagram).***

*Time (S)*

## **1.4 Conditions**

### **initial**

*Displacement is null in all the bar at the initial moment.*

2

### **Reference solution**

*The solution must show the absorption of a wave of compression by absorbing surface. imposed displacement is a uniform translation according to the  $x$  axis. One must obtain a field of identical displacement according to this direction in all the plans  $X = Cte$ . Moreover, the border absorbing is orthogonal with this axis. One thus studies the absorption of plane waves of compression under normal incidence. The theory [bib1] known as that with a solid paraxial border of order 0, this absorption is perfect. It is what one must check with this reference solution.*

*One thus goes, by observing the evolution of displacement in a given point of the grid, to stick to to find in the signal obtained the duration of excitation and the return at rest after the passage of the wave, characteristic of its absorption.*

2.1

### **Results of reference**

*One gives in this paragraph the results obtained with Code\_Aster in this configuration. One check that they are satisfactory and one takes them as reference for the future. They concern, for the case 3D, the bar being 200 m length, the evolution of displacement in  $X$  in a point of the bar located at 150 m of the face excited in direction  $X$  and at the center of the section in the  $yz$  plan. For the case 2D, the bar being 50 m length, the point is located at 40 m of face according to  $X$  and in the middle of the section in the direction  $y$  (in 2D, one takes a shorter grid and refined).*

**Time (S)**

*As envisaged, the width of the signal measured in both cases is identical to that of the function of excitation. Physically, one observes the wave propagation well of compression. The signal is little modified in its propagation and one thus finds well the maximum amplitude of 1 Misters One notes also clearly the return at rest immediately after the passage of the wave and the absence of signal thought of the end of the grid.*

## **2.2 Uncertainties**

*It is about a numerical result of the study. The qualitative forecasts are found. Values numerical are related to the precision of calculation. Only the return at rest is precisely given by analysis.*

***Summary of the results***

*One finds by calculation with two modelings quantitatively, the maximum of displacement equal to the maximum amplitude of the signal and qualitatively, the return at rest after the passage of the wave.*

*The results obtained with operators **DYNA\_LINE\_TRAN** and **DYNA\_NON\_LINE** are very close. The difference comes from obtaining to each step in time from the state from balance from the efforts from the second*

*member with operator **DYNA\_NON\_LINE**, which explains why its results are a little bit better even with a step of larger time. This difference remains however tiny because the step time used with **DYNA\_LINE\_TRAN** is sufficiently small.*

***Document: V2.04.121***

***SDLV121 - Wave planes shearing in one elastic column***

***Summary***

***One tests the application of a loading in transient in the form of a plane wave thanks to the elements paraxial rubber bands of order 0, in 3D and 2D. One applies this loading to an elastic solid mass occupying one half space and which one models a column. This column is supposed to be infinite in its lower part and***

***level in its part higher than the level of the surface of the free half space left. One observes propagation of the incidental wave, its reflexion on the free face of the solid mass and its absorption by the elements***

***paraxial at the lower end of the column.***

***One tests successively the two direct transitory operators of Code\_Aster, namely DYNA\_LINE\_TRAN and***

***DYNA\_NON\_LINE.***

## ***Problem of reference***

### ***1.1 Geometry***

***The system considered in the case 3D is that of a homogeneous elastic ground occupying the half space***

***$Z < 0$ . The plan  $Z = 0$  is left free. One models of this ground a vertical column, presumedly infinite in its lower part and levelling than the free face at its higher end. The elements are placed paraxial on lower surface, to translate the infinite character of the column and to apply it loading by plane wave. In the case 2D, the principle is identical, with a very broad column which one models only one vertical section (see diagram).***

***Moreover, the direction of vibration is the y axis in the case 3D. It is about the x axis in the case 2D.***

***Locate:***

### ***1.2 Properties***

***materials***

***Elastic solid mass: floor covering***

***Density:***

***1900 kg.m<sup>3</sup>***

***Young modulus:***

***4,44.10<sup>8</sup> Pa***

***Poisson's ratio:***

0,2

***1.3***

***Boundary conditions and loadings***

***One is interested in the movement 1D of the column under the exciting action of a wave planes vertical.***

***To identify this movement, one forces all the nodes of the same horizontal section to have it even displacement.***

***In this configuration, the loading by plane wave comprises the following characteristics:***

***Direction: (0. 0. 1. )***

***Type\_d' wave: "HS"***

***Outdistance initial origin: 150 m***

***Signal: function given below (with its derivative which is used as entry with calculation):***

**Reference solution**

***The propagation 1D of the signal of the incidental wave in the column is known analytically [bib1].***

***One***

***can for example determine the moment of passage of the maximum of the incidental wave with middle height, that is to say with***

***a 25 m depth, and that of the maximum of the wave thought of the same point.***

***Taking into account the signal given previously and position of its source to  $Z = 150$  m, the maximum signal is  $Z = 105.5$  m (i.e.  $150 -$  value of  $49,5$  m of the parameter corresponding) that is to say to  $50,5$  m of the paraxial surface ( $Z = -50$  m) of the column in direction  $Z$  (that of the wave) with the initial moment. To arrive to  $25$  m, it will thus have to traverse  $75,5$  m. the speed of the waves of shearing being of  $281$  m.s<sup>-1</sup> for the ground considered, one can thus await the maximum of displacement with middle height in the column for time  $0,27$  S. Moreover, at the time of the passage of the wave***

***reflected, the signal will have traversed  $50$  m moreover, therefore one can await it for time  $0,44$  S. the value***

***maximum measured at these moments must be 1 Meters Ce are these analytical values which one will test***

***in calculation.***

**2.1**

**Results of reference**

***One gives in this paragraph the results obtained with Code\_Aster in this configuration. One check that they are satisfactory qualitatively and quantitatively.***

***They concern, for the case 3D, the evolution of displacement in the three directions in a point of column located at middle height, is to  $25$  m of the free face in direction  $Z$ . The measurement of***

*displacement is identical in the case 2D.*

*Moreover, the direction of vibration is the y axis in the case 3D. It is about the x axis in the case 2D.*

-1,20E-03  
Time (S)

*It is checked first of all that displacements is null according to X and Z in the case 3D and according to y in the case 2D.*

*The celerity of the waves of shearing in a floor covering is of 280 m.s<sup>-1</sup> approximately. The length of signal is approximately 80 m. It is thus checked that the width of the peaks is well 0,3 S at the base. One also observes at the moments envisaged the presence of the two identical peaks due to the reflexion without change of sign on the free face. Their amplitude of 1 mm also finds the signal imposed.*

*The inversion of the sign of displacement in the case 2D is due only to the orientation of the reference mark.*

## **2.2 Uncertainties**

*It is about a numerical result of the study. One finds the qualitative and quantitative forecasts. numerical values are related to the precision of calculation.*

on a complete model (3D)***

***Summary:***

***It is about a linear test of dynamics 3D.***

***The goal is to test order PROJ\_MESU\_MODAL in the case of a system 3D. This order allows to project experimental dynamic transitory answers in a certain number of points on a basis modal of a numerical modeling.***

***This test contains 2 modelings:***

•  
*projection (of constraints) is done on a basic concept modal of type [mode\_meca],*

•  
*projection (of constraints) is done on a basic concept modal of type [base\_modale].*

*For 2 modelings, provided experimental measurements are identical and make it possible to test seek nodes in opposite and the taking into account of a local orientation.*

*In both cases, the reference solution is obtained by a direct calculation with Code\_Aster; projection is realized in the successful outcome where the number of modes is equal to the number of measurements. Answers in constraint obtained after projection are identical to the constraints of reference provided in data.*

*For modeling A, the answers in displacements and deformation obtained after projection are in perfect adequacy with the reference solutions. Values speeds and the accelerations deduced from identified modal contributions are close to those obtained by direct calculation. Weak variations noted are due to the errors of approximation generated by the determination via a linear diagram in time speeds and accelerations.*

## **1** **Problem of reference**

### **1.1 Geometry**

*Let us consider the embed-free slim cylindrical bar described below:*

**$P(T)$**

**$R$**

**$L$**

**Length**

**:  $L = 4\text{ m}$**

**Ray**

**:  $R = 0.1\text{ m}$**

**End 1: embedded ( $x=0$ )**

**End 2: free ( $x=l$ )**

### **1.2**

#### **Properties of materials**

*The characteristics of material are as follows:*

**Young modulus:  $E = 2.1 \cdot 10^{11}\text{ Pa}$**

**Poisson's ratio:  $= 0.3$**

**Density:  $= 7800\text{ kg/m}^3$**

### **1.3**

#### ***Boundary conditions and loading***

***The boundary condition is the embedding of end 1 of the bar. This embedding is of type beam to allow the effects Poisson on the section.***

***The loading applied for the calculation of answer is a thrust load, constant in traction, distributed on the section of end 2:***

$$P(T) = 0$$

***if  $T < 0$***

$$P = 106 \text{ NR}$$

***if  $T \geq 0$***

***0***

### **2**

#### ***Reference solutions***

##### **2.1**

***Method of calculation used for the reference solution***

***.***

***Analytical solution:***

***An analytical solution of this problem exists. It is described in:***

*In this case, the solution by modal superposition of this problem is written:*

*s-1*

*(*

*P*

*8P I*

*0*

*0*

*- 1*

*X*

*C*

*U X, T)*

*( )*

*=*

*X - 2*

*sin (2s -)*

*1*

*cos (2s*

*)*

*1*

*T*

*EA*

*EA*

*(2s -) 2*

*1*

*2I*

*-*

*2I*

*s=1*

*EA*

*with: C =*

*: propagation velocity of wave in the bar  
m*

*Adopted reference solution:*

*The analytical solution utilizing an infinite sum on the modes, it is preferable that reference solution and the solution with projection corresponds to the same configuration, with the same number of modes.*

*Moreover, to avoid problems involved in the discretization of the numerical grid, the solution of reference selected is the answer provided by the direct calculation carried out with Code\_Aster with order DYNA\_TRAN\_MODAL.*

## *2.2*

*Results of reference*

*For modeling A, the comparison of the results relates to displacements, speeds, accelerations, strains and stresses along axis X, of the nodes N2 and NR 4 to 3 moments different. NR 4 corresponds to a node of measurement and N2 is not one.*

*For modeling B, the comparison of the results relates to the constraints of the nodes NR 3 and NR 4 at 3 different moments.*

## *2.3*

*Uncertainty on the solution*

*The selected reference makes it possible to draw aside uncertainties related to the discretization of the numerical grid.*

*The number of modes of the base of projection is equal to the number of measurements, therefore the solution of the inversion is exact (in opposition to an approximate solution of a generalized opposite problem).*

*If projection is done on a concept of the type [mode\_meca], modal bases of reference solution and solution obtained by projection are identical, the answers in displacements, strains and stresses obtained must thus be similar to the answers of reference. Some errors of approximation can appear on speeds and accelerations which are determined by a linear diagram in time.*

*If projection is done on a concept of the type [base\_modale], modal bases of reference solution and solution obtained by projection contain the same number of modes but are different. The calculation of reference not being possible on a concept of the type [base\_modale], the comparison of the results relates only to answers corresponding to provided measurements.*

*Summary of the results*

*The results obtained are excellent since the instantaneous frequency deviations with the reference solution*

*are lower than 0.03%. Moreover, Code\_Aster detects well the 6 modes of rigid body, which one does not have*

*not asked to calculate.*

*To calculate the rigid modes indeed, two possibilities exist. With the option “BANDAGES” on frequency band (0, 3000 Hz), one can employ either the method of “SORENSEN”, or the method LANCZOS (“TRI\_DIAG”) by specifying option “MODE\_RIGIDE”.*

**Handbook of Validation**

**V2.05 booklet: Linear dynamics of the assembled structures**

**Document: V2.05.002**

**SDLX02 - Piping: Problem of Hovgaard.**

**Spectral analysis**

**Summary:**

The three-dimensional problem consists *firstly*, to seek the modes of vibration of a mechanical structure composed of a curved beam embed-embedded (problem of Hovgaard), *secondly*, to analyze the answer of this structure subjected to a spectrum of acceleration. This test of mechanics of the structures corresponds to one

analyze dynamic of a linear model (assembled structure) having a linear behavior. It includes/

understands

three modelings.

Via this problem, one tests the element of beam of Timoshenko (right beam or curve) in inflection, the calculation of the clean modes by the method of Lanczos, the calculation of the static modes and calculation of a spectral response of a structure subjected to a spectrum of acceleration (one tests also the interpolation of spectrum).

The results obtained are in concord with the results of reference (compilation of results obtained by other software packages).

## **2 Reference solution**

### **2.1 Method of calculation used for the reference solution**

Averages of codes: Lice, ADL, TITUS-T.

Guide validation of the Software packages of structural analysis - AFNOR - 1990 (for modal calculation).

values provided in the card under are estimated and were corrected thereafter in 1992. However, they were preserved for calculations with matrix of diagonal mass.

### **2.2 Results of reference**

Modal calculation:

the first 9 Eigen frequencies.

Spectral answer:

displacement of the nodes N3 N5 and N7, N9, N11.

Reaction of supports to the nodes N1, N15.

Generalized efforts of the nodes N3, N7, N11.

### **2.3 Uncertainty on the solution**

About 1% on the first 5 modes.

Between 1 and 2,5% for modes 6 to 9.

## **9 Summary of the results and remarks general**

### **Modal calculation:**

The results are in conformity with the card of validation.

By refining the grid (modeling C) one obtains correct results.

**Spectral answer:**

The results are in conformity with the results of reference (the error is lower than the thousandths).

***Handbook of Validation***

***V2.05 booklet: Linear dynamics of the assembled structures***

***Document: V2.05.003***

***SDLX03 - Assembly of rectangular plates  
thin braced***

## **Summary:**

***This three-dimensional problem consists in seeking the frequencies of vibration of a mechanical structure composed of an assembly of plates where one simulated an effect of stiffening. This test of Mechanics of Structures corresponds to a dynamic analysis of an assembled structure having a linear behavior. It includes/understands two modelings.***

***Via this problem, one tests the element of plate DKT as well as the calculation of the frequencies of vibration by the method of Lanczos with detection of the modes of rigid body.***

***In the second modeling, one tests in more the connection between hulls (key word LIAISON\_COQUE of order AFFE\_CHAR\_MECA).***

***The results obtained are in concord with the results given in guide VPCS (average of results obtained by various computer codes). The six modes of rigid body were indeed detected. A comparison with experimental results is also satisfactory.***

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**The reference solution is that given in card SDLX03/89 of guide VPCS.**

**The reference solution was obtained by experimental study of the frequencies and clean modes free structure on a model produced with welded sheets.**

**The structure suspended by flexible connections is put in vibration by a discharger electrodynamics. The statement of the Eigen frequencies is obtained starting from an accelerometer.**

**In addition, of the digital simulations, carried out by various computer codes, allowed to establish “results of reference” for the models finite elements.**

**2.2**

**Results of reference**

**the first 6 nonnull Eigen frequencies.**

**2.3**

**Uncertainty on the solution**

**Lower than 4%.**

Document: V2.05.100***

***SDLX100 - Transitory response of a plate  
with a field of pressure resulting from ENSIGHT***

***Summary:***

***The applicability of this test relates to the dynamics of the structures, and more particularly the calculation of linear transitory response direct to a field of pressure evolving/moving in time, defined in files with format ENSIGHT. It includes/understands a modeling.***

***It is a question of calculating the response of an element of hull supported in its 4 nodes out of 4 stiffnesses and shock absorbers, with a sinusoidal pressure defined in the four nodes.***

***This test makes it possible to validate the tools of definition of loading of pressure starting from files to the format ENSIGHT and of calculation of direct transitory response to this loading.***

***The results obtained are in very good agreement with the analytical reference solution.***

### ***1.2***

***Material properties***

***Material of the plate:***

$$\begin{aligned} E &= 2.1 \times 10^{11} \text{ Pa} \\ &= 0.3 \\ &= 7800 \text{ kg/m}^3 \end{aligned}$$

Comes out from linear elastic translation one-way:  $K = 9.8696 \text{ E}+4 \text{ N/m}$   
One-way viscous damping:  $C = 3.1416 \text{ N (m/s)}$

These values correspond to a reduced damping of 1% on the first mode of the structure.

### 1.3

#### Boundary conditions and loadings

Sinusoidal uniform pressure applied to the plate along axis X, defined by a value in the four nodes:

$$\begin{aligned} P &= P_0 \sin T \\ &= 2 F, \\ F &= 100 \text{ Hz} = \text{first Eigen frequency of the system.} \end{aligned}$$

#### P0

$= 1 \text{ N/m}^2$  is a total force on the F0 plate  $= a^2 P = 1 \text{ N}$   
constant

### 1.4 Conditions

#### initial

Structure initially at rest.

***SDLX301 - Building with floor-columns***  
***dissymmetrical subjected to a horizontal excitation***

***Summary:***

***Applicability: seismic calculation. Type of analysis: spectral and combinations.***

***A number of modelings: 1.***

***Description: three-dimensional study of a building with 3 floors out of 9 columns, embedded at the base of***

***columns, with unbalance, subjected to a horizontal seismic excitation in displacement. The distribution***

***offset of the masses of the floors allows to break symmetry, to couple the geometrical directions principal and to generate an effect of torsion. The values of reference are obtained with the code CASTEM 2000 and the SAMCEF software, which have slightly different methods.***

***The columns are modelled by beams, and the floors by elements of plane hull. Eights first clean modes are preserved for calculations of modal recombination. Objective: to test them displacements, interior efforts, and reactions to the embedding of a column for the recombinations modal CQC, SRSS, DSC. Precision of the results: comparison between codes. Strong tolerances are allowed for certain computed fields whose values are several weaker orders of magnitude.***

## **Reference solutions**

2.1

### **Method of calculation used for the reference solutions**

*The calculations taken for reference are carried out with codes CASTEM 2000 and the SAMCEF software. The solution*

*of reference is not given by the results of [bib1] because it missed in this reference some geometrical characteristics and of material to remake with identical the model of the structure studied. Certain data retained in this case test are thus different from those of the report/ratio [bib1], what does not allow a comparison of the results.*

2.2

### **Results of reference**

.

*Frequencies calculated with CASTEM 2000 and the SAMCEF software,*

.

*Spectrum of response in displacement for a damping from = 5%,*

*· Déplacements by modal recombination CQC, SRSS, DSC for the column B (calculated in taking into account the first 8 modes primarily torsion of the building and inflection of columns, but the floors are bent little),*

.

*Dynamic and pseudo fashion for the static correction,*

.

*Efforts with the embedding of the column B and the central column E,*

.

*Interior efforts along the column B.*

## ***Results of modeling A***

### ***4.1 Remarks***

***For a given node I, effort generalized for element I - 1 and for element I is compared respectively in tables “low” element and “high” element.***

***The efforts are given in the local reference mark of the elements of beam (principal reference mark of inertia).***

**Note:**

***The standard of error of the modes calculated by the method of Sorensen de Code\_Aster is always lower at 10-9.***

**Note:**

***The total mass of the building is 132552 kg; the strong orientation according to of the modes is due to the relative one there less inertia according to there of the columns. Effective modal mass cumulated in direction X of the seism obtained by Code\_Aster 97.678% of the total mass represent.***

**Note:**

*The differences between modelings and software are rather strong in direction Z, because it is little solicited in these modes.*

**Summary of the results**

**Comparison with CASTEM 2000:**

*The variations on the Eigen frequencies calculated with CASTEM 2000 and Aster are lower than 1,4%. The double mode was separate in two close modes (6 and 7) of which one is a dominating mode according to the axis y (mode 6) and the other according to X (mode 7); the variation on the effective*

*modal masses (in %)*

*very high according to X for mode 6 and according to there for mode 7, is not relevant being given the weak one weight of these directions in the modes considered.*

*The variations obtained on calculation with the spectral method, for displacements remain broadly lower than 8%, the variations on the reactions to the embedding of the columns B and E are broadly lower than 11% (without taking account of the moment of reaction according to Z), and variations on generalized efforts remain overall lower than 7% (without taking account of the torque). Strong tolerances are allowed for certain computed fields whose values are of several weaker orders of magnitude.*

***Comparison with the SAMCEF software:***

*The method of resolution adopted in the SAMCEF software is based on the method known as of the ground node.*

*This method consists in binding to a single node all the nodes which are interdependent of the foundation. It*

*node is affected of a mass in translation which is worth 1000 times the mass of the structure. displacements deferred in the tables are not corrected effects of residual masses which are results also available.*

*The variations on the Eigen frequencies calculated with the SAMCEF software and Aster are lower than 3,2%.*

*type of element of hull used (deformable or not with the sharp effort) influence the result, it goes from there from*

*even of the smoothness of the grid of the floors. Variations on the Eigen frequencies going until 10% were observed by initially taking a coarser grid for the floors, made up of 345 nodes and 516 elements including 108 elements of right beam of Timoshenko and 408 elements hull DKT. Modes 6 and 7 represent a mode doubles of which percentage of modal mass effective 4% in the direction X and 2% in direction Y. do not exceed.*

*Variations obtained on calculation with the spectral method, for displacements in the direction excitation remain overall lower than 10,5%. For the reactions to the embedding of column B, these variations are overall lower than 30%. They reach 80% for the column E, however for the reaction according to axis X and the moment according to the axis y, they remain lower than 18%.*

*reaction of torsion of the columns is not null. Variations in connection with the efforts generalized in direction of the excitation remain overall lower than 26%. On the other hand, a different coupling between the directions of the excitation introduces important variations on the efforts into the directions transverses with the excitation.*

*Strong tolerances are allowed for certain computed fields whose values are of several weaker orders of magnitude.*

**Note:**

.  
*the form of the function describing the spectrum in displacement strongly depends on Eigen frequencies  $f_i$  for which the peaks of displacement are given. In consequence, a shift of the calculated Eigen frequencies disturbs the answer seismic in entry of the data and an effective comparison of calculations does not allow,*

.  
*the results of generalized efforts are expressed in the local reference mark of the beams and corrected static effects.*

***SHLL100 - Harmonic response of a bar***  
***by dynamic under-structuring***

***Summary:***

***The applicability of this test relates to the dynamics of the structures, and more particularly the calculation of harmonic response by dynamic under-structuring.***

***It is a question of calculating the harmonic response in traction and compression of a embed-free beam modelled by elements of the type “bars”. The modelled structure is deadened (damping of Rayleigh by elements).***

***The results of reference result from a direct harmonic calculation. This test thus makes it possible to validate the tools of calculations of harmonic response per under-structuring established in Code\_Aster and more particularly:***

***.  
the catch in depreciation account by element,***

***.  
the calculation of the second member including the harmonic loading,***

***.  
restitution of the harmonic response on a grid skeleton, including the fields of displacement, speed and of acceleration.***

*The bar is cut out in 2 parts of equal size. Each substructure considered is with a grid in segments to which are affected elements “bars”.*

*The structure is studied using the method of the harmonic under-structuring with interfaces of HARMONIC type CRAIG-BAMPTON.*

*The modal base used is made up of 4 clean modes for the substructure of right-hand side, of 5 clean modes for the substructure of left to which are added the constrained modes harmonics associated with the interfaces (calculated to 300 Hz. This value of the pulsation does not have any influence on the result, it is arbitrary [bib3]).*

*SHLL101 - Right beam. Analyze harmonic*

***Summary:***

*This two-dimensional problem consists in calculating the efforts present in a beam subjected to a*

*traction or*

*with an inflection during a harmonic analysis. The reference solution is obtained starting from the equations discretized.*

*This test comprises two modelings.*

*For the first modeling, four requests are tested:*

- force of traction,*
- force of traction and material presenting a damping,*
- strength flexural,*
- strength flexural and material presenting a damping.*

*For the second modeling, two requests are tested:*

- force of traction,*
- force of traction and material presenting a damping.*

*The second modeling makes it possible to test the complex loadings imposed by the order AFPE\_CHAR\_MECA\_C.*

*Handbook of Validation*

## **2.2**

### **Results of reference**

*The results of reference are displacements, speeds, accelerations and the efforts generalized obtained at the point B during the harmonic analysis.*

## **2.3**

### **Notice for modeling B**

*For modeling B, one wants to test the problem in traction in the case of key word FORCE\_POUTRE who allows to apply efforts distributed. To obtain the same solution as the beam subjected to nodal force in its end, the relation between the effort distributed constant and the nodal force is:*

*F L*

*F ( )*

*B =*

*X*

*2*

*With the values given to the 1.3, one a: F = 600 N/m*

***Harmonic response of a under-structured plate***

## **Summary:**

*This case-test treats taking into account of random uncertainties for the calculation of a harmonic answer by under-structuring of the type Craig Bampton. We take again here an example of the literature made up of one plate supported at its ends.*

*The functionality of operator GENE\_MATR\_ALEA consisting in is tested taking for entering concept one*

*concept macr\_elem\_dyna of a given substructure and to produce a random macr\_elem\_dyna (mass, stiffness and damping). The concepts macr\_elem\_dyna random products then make it possible to calculate*

*for example the field of confidence of the harmonic response of the plate.*

 $[D] = a [M] + B [K]$  with  $A =$   
and  
 $B =$   
,  
 $\max + \min$   
 $\max + \min$

where  $\omega = 0.04$ ,  $\min = 5.2$  rad/s and  $\max = 212.8$  rad/s.

### 1.3 **Boundary conditions and loadings**

The flexbeam is in simple support on its four edges.

Substructure 1 is subjected to an effort external with the item (0.24, 0.24) equal to 1N on the tape of analysis [0, 2 .100] rad/s according to direction Z and null on other DDLs and for the others frequencies.

### 1.4 Conditions initial

The dynamic system is initially at rest.

### 2 **Reference solution**

## **2.1**

### ***Method of calculation used for the reference solution***

*The method used is the method published in particular in [bib1] (cf [§2.3]). Uncertainties random of the dynamic system are modelled by using the probabilistic model said not parametric of uncertainties due to Soize (cf [bib1]). Statistics on the harmonic answer of linear dynamic system are obtained by the method of Monte Carlo. The procedure is identical with that presented to [§ 3.3], but developed under Matlab.*

*In the standard commodity, 500 pullings are carried out and the envelopes lower and higher of these 500 pullings are presented.*

## **2.2**

### ***Results of reference***

*The ddls of observation correspond to direction DZ of the node of co-ordinates (0.39, 0.31) for first substructure and of the node of co-ordinates (0.79, 0.24) for the second substructure.*

*The results of reference are given in the form of the graphs below drawn from [bib1].*

*Node (0.39, 0.31), DZ*

*Node (0.79, 0.24), DZ*

### ***Inter-quantiles fields (milked thin) of displacements to the ddls of observation***

#### ***Results of reference***

*(the fatty features are approximations, not used here for the comparison)*

## **2.3 Reference**

### ***bibliographical***

### ***3 Modeling***

#### ***With***

#### ***3.1***

##### ***Characteristics of modeling***

###### ***Modeling: DKT***

*The average model with the finite elements of the plate consists of a regular rectangular grid whose step is constant and is worth 0.01m in the directions X1 and X2. Consequently, all elements stop are identical and each one is an element plates with 4 nodes.*

###### ***Modeling: DIS\_T***

*The concentrated masses and the concentrated stiffness are modelled by elements DIST\_T.*

#### ***3.2***

##### ***Characteristics of the grid***

*The average model finite elements comprises 14849 active degrees of freedom, including 8840 for substructure, 1, 5860 for substructure 2 and 149 for the interface.*

*A number of degrees of freedom:  $8840+5860+149$*

*A number of finite elements: 6000 QUA4 et3 DIS\_T*

#### ***3.3***

##### ***Method of calculation***

###### ***Small-scale model***

*As for the reference, we take for each substructure 20 modes in order to have good convergence of the calculated response with respect to the number of modes.*

## ***Achievements of the random matrices of the nonparametric probabilistic model by under structure***

*For each under structures, reduced matrices of masses, stiffnesses and dissipation of model means are replaced by achievements of the random matrices of mass, stiffnesses and of dissipation according to the nonparametric probabilistic model. For that, we use the generator random matrices GENE\_MATR\_ALEA which generates a concept macr\_elem\_dyna from one macr\_elem\_dyna average.*

*One can thus allot to each substructure a level of uncertainty by fixing the parameters of dispersion for each substructure. We fixed them at 0.1 for each matrix of masses, of stiffnesses and generalized damping and for each substructure.*

### ***Resolution of the probabilistic linear dynamic system.***

*Operator DYNA\_LINE\_HARM is used to build the harmonic response of the plate for each random realization of the matrices of mass, stiffness and dissipation.*

*The frequential interval of the study is  $B = [0, 100]$  Hz, with a step of 0.5 Hz.*

### ***Construction of the statistical estimates.***

*After each call to DYNA\_LINE\_HARM, we have a realization of the fields of displacement. With each pulling (iteration of Monte Carlo) we build the statistical estimates with the assistance only of operator CALC\_FONCTION and key words WRAPS, POWER and COMB.*

### **3.4 Functionalities tested**

#### **Orders**

#### **GENE\_MATR\_ALEA**

*The functionality tested of GENE\_MATR\_ALEA is the possibility of producing a concept of the type macr\_elem\_dyna starting from an other concept of the macr\_elem\_dyna type.*

### **3.5**

#### **Sizes tested and results**

*The initial validity of the case test was established by graphic comparison with the bibliographical reference data in [§2.2]. The answers are calculated into 1 point for each substructure; these points have for co-ordinates: (0.39, 0.31) and (0.79, 0.24).*

*As for the reference, the envelopes lower and higher of 500 pullings are calculated. For each frequency, the inter-quantile field corresponding corresponds, for example with a level of confidence of 0.95, with a probability of 0.994 for the maximum value and 0.006 for the value minimal.*

*The results obtained with Code\_Aster are represented on the curves below:*

*Node (0.39, 0.31), DZ*

*Node (0.79, 0.24), DZ*

### **3.6 Comments**

*The various statistical estimates are not converged here. Only 3 simulations of Monte Carlo were made drastically to reduce time CPU of the case test. Convergences having been validated on the study supplements (after convergence, the statistical estimates calculated with to start from Code\_Aster correspond to the results given by the cf graphs, standard commodity), case test is satisfied with nonthe regression.*

4

### **Summary of the results**

*The results obtained are completely in conformity with those of the bibliographical reference [§2.2] obtained entirely in Matlab.*

## 5.4 Remarks

The pressure has a negative sign (instead of positive) because the faces of the elements 3D are badly directed.

- The grids for the elements of order 1 are not fine enough.
- The results are more precise with elements of order 2.
- The problem is adapted more to an axisymmetric modeling (H, I, J) - > better results.
- Results of the elements 3D and the plane elements having spaces of interpolation in correspondence are identical.
- The results of axisymmetric elements QUAD8 and QUAD9 are identical.

**Document: V3.01.010**

**SSL10 - Gantry with side connections**

**Summary:**

Static test in linear elasticity, being used to validate the elements of right beam POU\_D\_T for a loading specific and a loading distributed (key word FORCE\_POUTRE).

The relations and moments bending are tested.

*SSL11 - Lattice of pin jointed struts under load specific*

*Summary:*

*This test makes it possible to check the elements of bar and beam for the structural analysis out of lattice. The lattice considered is plane. Calculation is static, elastic, linear. The reference solution is analytical.*

*Three modelings make it possible to test elements  $POU\_D\_T$  with and without rotulées connections, as well as*

*elements BARS.*

***SLL14 - Plane gantry articulated in foot***

***Summary***

***This test relates to the study of a gantry made up of hurred beams, articulated in foot, in static analysis linear.***

***The gantry is modelled with elements linear (SEG2) and subjected to four loadings (distributed or specific).***

**B**

**X**

**L**

**Sections AD, EB**

**$I1 = 5. E4 \text{ m}^4$**

**Sections cd., EC**

**$I2 = 2.5 E4 \text{ m}^4$**

*The gantry consists of symmetrical beams of sections, so that  $IY=IZ$ .*

*One takes account only of the energy of inflection, because the beams are very slim. This is why them other characteristics of section of beam do not intervene.*

## **1.2**

## ***Material properties***

*Isotropic linear elastic material:*

$$E = 2.1 \text{ E11 Pa}$$

## **1.3**

### ***Boundary conditions and loadings***

*Feet of articulated posts A and B.*

### ***Loadings***

*Nodal force out of C:*

$$F_y = 2000 \text{ NR} = F1$$

*Nodal force in D:*

$$F_x = 10.000 \text{ NR} = F2$$

*Moment in D:*

$$M_X = 100.000 \text{ N.m} = M$$

*Force distributed on section cd.:*

$$P_z = 3000 \text{ N/m}$$

### **Summary of the results**

*The results obtained with modeling POU\_D\_E are in very good agreement with the solution analytical and thus validate the calculation of lattice of beams subjected to efforts specific or distributed.*

**Document: V3.01.100**

**SSLL100 - Symmetrical structure of beams  
with an elbow**

**Summary:**

*This test in statics, linear elasticity makes it possible to validate the elements of rectangular beam and curves in inflection*

*plane, as well as the discrete elements. Four loadings are defined, of which some in local reference mark.*

*Two modelings make it possible to test on the one hand the right elements (the elbow is modelled using 20*

*right elements) and in addition right and curved elements.*

*The reference solution results from the file of validation of the code LICE. Results obtained with Code\_Aster are very close (lower deviation than 2.104 for modeling to the arc of circle with POU\_C\_T, a little higher variation (3%) for that with POU\_D\_T, which is due to a too coarse discretization).*

### **Summary of the results**

*The results obtained with Code\_Aster coincide well with those of the code LICE (solution of reference) in particular for modeling A (POU\_C\_T).*

*For modeling B, they are very close also ( $< 4 \cdot 10^4$ ) except in the case of load to gravity (3% of variation to the maximum) because of the dependence of the solution to the smoothness of discretization.*

*This test thus validates element POU\_C\_T.*

***V3.01 booklet: Linear statics of the linear structures***  
***Document: V3.01.101***

***SSLL101 - Piping: Problem of HOVGAARD***

***Summary:***

***It is about a linear elastic test, in statics, of a noncoplanar three-dimensional piping comprising elbows. There is a test in dynamics of same structure (SDLX02) [V2.05.002].***

***One tests elements POU\_D\_T, POU\_C\_T, PIPE (SEG3 and SEG4) and TUYAU\_6M (SEG3) by the intermediary of five modelings, each elbow is represented by:***

- .  
20 elements POU\_D\_T in modeling A,***
- .  
2 elements POU\_C\_T in modeling B,***
- .  
28 elements PIPE (SEG3) in modeling C,***
- .  
28 elements TUYAU\_6M (SEG3) in modeling D,***
- .  
28 elements PIPE (SEG4) in modeling E.***

***The loadings are:***

***.  
gravity,***

.  
*thermal dilation,*

.  
*nodal forces.*

## ***Reference solution***

***2.1***

### ***Method of calculation used for the reference solution***

*The reference solutions adopted to check Code\_Aster modelings are as follows:*

- for modelings BEAM: comparison with the codes: LICE, ADL and TITUS-T [bib1], using a modeling of the beam type,*
- for modelings PIPES: comparison with code ABAQUS, using one modeling of the pipe type. The number of mode of Fourier (M) used during calculation of reference is identical to that used during calculations with Code\_Aster.*

## ***12.2 Remarks***

***The grid in SEG4 is obtained starting from a grid SEG3 with order CREA\_MAILLAGE, MODI\_MAILLE with option "SEG3\_4". It is important that the node medium of the SEG3 is well with medium, Code\_Aster checks this condition with a tolerance.***

***The results obtained with Code\_Aster are similar to those of ABAQUS with elements pipes except for displacement DY (actual weight and nodal force) or the variation is about 5% and 2%.***

*13 Summary of the results*

*Modeling beam:*

*The results are similar to the reference solution (modeling beam: average of results of 3 codes) as well for modeling A, where each elbow is discretized by 20 right elements, POU\_D\_T, that for modeling B, where one uses the elements curves POU\_C\_T. One notes simply, in this case, a variation a little more important in a value of displacement (0.65%).*

*Modeling pipe:*

*The Code\_Aster results are similar to those of ABAQUS (for elements pipes), except for displacement DY and for the loadings actual weight and nodal forces where the variation with the solution of*

*reference is more important with meshes SEG3 (10%) than with meshes SEG4 (5%).*

*The loading of dilation gives similar results.*

*This case-test makes it possible to test a noncoplanar piping.*

**V3.01 booklet: Linear statics of the linear structures**

**Document: V3.01.102**

**SSLL102 - Fixed beam subjected to efforts  
unit**

**Summary:**

*This test allows a simple checking of calculations of right beams and hull 1D in mechanics of the structures linear statics. The model is linear.*

*· 7 modelings make it possible to test the various types of elements of rectangular beams in Code\_Aster.*

*For each modeling, one calculates simultaneously 3 beams of different sections: rectangle, circle, angle.*

*Modeling A makes it possible of more than test the change of reference mark: the beam is directed according to trissectrice with the total reference mark.*

*Modeling E tests the loading distributed on voluminal edges of elements.*

*Modeling F corresponds to a loading distributed varying linearly with modeling POU\_D\_E.*

*Modeling G corresponds to a loading distributed varying linearly with modeling POU\_D\_TG.*

*· Modeling H makes it possible to test the element of hull 1D (COQUE\_C\_PLAN) subjected to loads unit.*

*· Modeling I makes it possible to test a loading distributed varying linearly with modeling TUYAU\_3M.*

*The values tested are the generalized displacements, efforts and the constraints.*

## ***18.2 Remarks***

*The width for modeling COQUE\_C\_PLAN is imposed on 1 in Code\_Aster. In consequence, we multiplied by 0.1 the Young modulus to take account of the real width of*

*the beam. This width of 1 modifies the inertia of the beam and consequently the value of the constraint  $xx$  which is 10 with times lower than the value of reference. Moreover, for displacements, the results differ from modeling A because of the change of reference mark.*

## **21 Summary of the results**

***This test makes it possible simultaneously to check the correct operation of elements POU\_D\_E, POU\_D\_T and***

***POU\_D\_TG on 3 types of different sections. The perfect coincidence of the results with the solutions analytical (RDM) is normal, and must always be observed, since the solution is contained in functions of form of the elements.***

***Moreover, modeling E makes it possible to test the loading distributed on edges of elements voluminal. The variation with the analytical solution (RDM) is lower than 0.6%.***

***Modelings F, G and I make it possible to test the loading distributed (linear variation) for elements of beam POU\_D\_E, POU\_D\_TG and pipe sections. The variation with the analytical solution (RDM) is lower than 0.6%.***

***For modeling COQUE\_C\_PLAN the results are satisfactory (displacements and constraints)***

*for the unit loadings of extension type and inflection (imposed moment). For the loading of inflection (load imposed at an end) the error on displacement is weak 0.5%. It is more important on the constraint: 3.6%.*

*7*

## **Summary of the results**

*The analytical solution gives us 3 modes of buckling of which the critical loads are roots of an equation of the 3° degree.*

*Y-a it of other critical loads intercallées between the 3 found values?*

*Aster finds the good critical loads, but in the middle of much of others... for example for case 3, the 3 sought critical loads corresponds to the nume\_mode: 1, 10 and 19!*

*This is true for two modelings.*

### ***11 Summary of the results***

***The results of 4 modelings are very close to the reference solution which is an average results of 8 codes. One notes a small effect due to warping since the results of modeling C (POU\_D\_TG) are slightly different from the others, while remaining with less than 2% of reference.***

**Handbook of Validation**

**V3.01 booklet: Linear statics of the linear structures**

**Document: V3.01.106**

**SSLL106 - Right pipe**

**Summary:**

***This test allows a simple checking of the right pipe sections in static mechanics of the structures linear.***

***The model is linear.***

***For each modeling, 6 types of loading are applied at the end: a traction, 2 efforts edges, 2 moments bending and a torsion. One applies moreover one internal pressure, a linear force distributed and a thermal expansion.***

***The values tested are displacements, the efforts with the nodes, and the constraints and deformations at the points of Gauss. The reference solution is analytical (RDM).***

**Two modelings (A and B) make it possible to test the element PIPE with 3 modes of Fourier (modeling**

**TUYAU\_3M)**

**: modeling A uses MECA\_STATIQUE, modeling B uses STAT\_NON\_LINE (elastic behavior).**

**Two modelings (C and D) make it possible to test the element PIPE with 6 modes of Fourier (modeling TUYAU\_6M).**

**Two modelings (E and F) make it possible to test the element PIPE with 3 modes of Fourier and 4 nodes (modeling TUYAU\_3M).**

#### **4.2 Remarks**

*The values of shearings corresponding to the shearing action are not precise for this modeling. This is due to the functions of interpolation of order 2 of this element, for displacements of beam and rotations of beams. As transverse shearings of beam are obtained by:*

*duy*

*= -*

*, and that for the pure bending, rotations vary like polynomials of order 2,*

*xy*

*Z*

*dx*

*but displacements, like polynomials of order 3, which is badly approached by the functions of interpolation. The derivative of displacements is thus not precise.*

## 8.2 Remarks

*The values of shearings corresponding to the shearing action are not precise for this modeling. This is due to the functions of interpolation of order 2 of this element, for displacements of beam and rotations of beams. As transverse shearings of beam are obtained by:*

*duy*

*= -*

*, and that for the pure bending, rotations vary like polynomials of order 2,*

*xy*

*Z*

*dx*

*but displacements, like polynomials of order 3, which is badly approached by the functions of interpolation. The derivative of displacements is thus not precise.*

## **12.2 Remarks**

*The values of shearings corresponding to the shearing action are precise for this modeling. This is due to the functions of interpolation of order 3 of this element, for displacements of beam and rotations of beams.*

## **14.2 Remarks**

***The values of shearings corresponding to the shearing action are not precise for this modeling. This is due to the weak discretization for this modeling (only one element).***

## **15 Summary of the results**

***This test makes it possible to check the correct operation of the element PIPE (3 modes and 6 modes of Fourier) in linear elasticity, with operators MECA\_STATIQUE and STAT\_NON\_LINE, for the whole of loadings applicable to this element.***

***The variations compared to the analytical reference solution (solution in assumption of beam) are very weak for displacements (0,04% to 0,06%), except for the loading of pressure where the variation of 3% is due to the fact that  $W_0$  represents an average radial displacement. Actually this radial displacement varies in the thickness. The variation on the strains and the stresses (~ -1%) is more important than that on displacements but remains acceptable taking into account the fact that these values are calculated in points of integration located in the thickness of the pipe.***

***Document: V3.01.107***

***SSLL107 - Validation of MACRO\_CARA\_POUTRE***

***Summary:***

***The whole of modelings of this test make it possible to validate the macro\_commande calculation of characteristics of section of beam, MACRO\_CARA\_POUTRE, for all the options suggested. Sections studied are different according to modelings.***

- Modeling A validates the calculation of the characteristics of section of a corner type.***
- Modeling B validates the calculation of the characteristics of a circular section.***
- Modeling C validates the calculation of the characteristics of a rectangular section.***
- Modeling D validates the calculation of the characteristics of an alveolate rectangular section.***
- Modeling E validates the calculation of the characteristics of an octagonal section.***
- Modeling F validates the calculation of the characteristics of a circular section with a sequence on a calculation of beam.***
- Modeling G validates the calculation of a network of 2 rectangular beams of section.***

- *Modeling H validates the calculation of the characteristics of a mean section out of U.*
- *Modeling I validates the calculation of the constant of torsion for a perforated section.*

**1**

**Problem of reference**

**1.1 Geometry**

*The geometry of the various sections is provided via a plane grid. It are different for each modeling, and will thus be described in the corresponding paragraphs.*

*Modeling G also implements the chained calculation of the characteristics of a section circular, and the use of these characteristics in a calculation of a right beam, L=1m length, in pure traction.*

**1.2**

**Material properties**

*Without object, except for modeling G, where the treated beam has a Young modulus of 2.E11Pa and one*

*Poisson's ratio of 0.3.*

**1.3**

**Boundary conditions and loadings**

*Without object, except for modeling G: the right beam is embedded at an end, and is subjected to*

*the other end with a tractive effort  $F=1000N$ .*

2

## **Reference solution**

2.1

### **Method of calculation used for the reference solution**

*Since the solutions are specific to each modeling, they are described in corresponding paragraphs. They are drawn mainly from [bib1] and [bib2];*

2.2

### **Results of reference**

*One describes here the characteristics calculated by MACRO\_CARA\_POUTRE [R3.08.03]:*

#### *· Caractéristiques geometrical of the sections*

*1) In reference mark OXY of description of the grid 2D for the grid provided by the user*

- surface: AIRE\_M*
- position of the centre of gravity: CDG\_X\_M, CDG\_Y\_M*
- moments and product of inertia of surface, in the centre of gravity G in reference mark GXY: IX\_G\_M, IY\_G\_M, IXY\_G\_M*

*2) In the same total reference mark, for the grid obtained by symmetrization if SYME\_X or SYME\_Y:*

- surface: SURFACE*
- position of the centre of gravity: CDG\_X, CDG\_Y*
- moments and product of inertia of surface, in the centre of gravity G in reference mark GXY: IX\_G, IY\_G, IXY\_G*

*3) In the principal reference mark of inertia GYZ. cross-section, whose denomination corresponds to that used with the description of the elements of neutral fibre beam GX [U4.24.01].*

- principal moments of inertia of surface in reference mark GYZ, usable for the calculation of rigidity of inflection of the beam: IY\_PRIN\_G and IZ\_PRIN\_G*
- angle of flow of reference mark GXY to the principal reference mark of inertia GYZ: ALPHA*
- characteristic distances, compared to the centre of gravity G of the section for calculations of maximum constraints: Y\_MAX, Y\_MIN, Z\_MAX, Z\_MIN and R\_MAX.*

*4) In the total reference mark, in a point P provided by the user:*

- X\_P Y\_P: not calculation of the moments of inertia*
- IX\_P IY\_P IXY\_P: moments of inertia in reference mark PXY*
- IY\_PRIN\_P IZ\_PRIN\_P: moments of inertia in reference mark PYZ.*

## **9 Modeling**

### **D**

#### **9.1**

##### ***Characteristics of modeling***

*Hollow rectangular section. This modeling makes it possible to test MACRO\_CARA\_POUTRE to calculate*

*geometrical and mechanical characteristics of a level surface.*

*Two calculations are carried out:*

- first is carried out with the key word SYME\_Y = “YES”, i.e. that the section considered is obtained by symmetry around the axis Y (alveolate section). Moreover inertias are calculated compared to the point of co-ordinates (0, 0.025) (key word ORIG\_INER),*
- second is carried out without symmetry, on the section with a grid, with a calculation of inertias with center grid, C of co-ordinates (0.005, 0), and 2 different groups of meshes, which correspond each one to the vertical half of the grid (on both sides of the axis Cy).*

#### **9.2**

##### ***Characteristics of the grid***

*40 meshes QUAD4.*

*Co-ordinates of the nodes tops of rectangle are:*

*N1 0.00E+00 2.50E02*

*N2 0.00E+00 2.50E02*

*N3 1.00E02 2.50E02*

**15.1 Characteristics of modeling**

*Full rectangular section, of width 0.02m and height 0.05m. It is divided into two rectangles respective heights 0.025m, in order to test the calculation of the characteristics on groups of meshes for a network here made up of two parallel beams, ranging between two floors distant of  $L=0.0002$  (what makes it possible to obtain characteristics (coefficient of shearing) very close to that of the complete section).*

**SSLL108 - Discrete elements 2D**

**Summary:**

*The problem is quasi-static linear in mechanics of the structures.*

*One analyzes the response of a bar, modelled by 10 discrete elements, with a loading of traction, for to validate the two-dimensional discrete elements.*

*Only one modeling uses at the same time operators MECA\_STATIQUE, and STAT\_NON\_LINE, to validate the use of these elements (of which the behavior remains linear) with other finite elements with behavior unspecified.*

## **1** **Problem of reference**

### **1.1 Geometry**

*A bar  $L=10m$  length, along axis  $X$ , modelled by 10 discrete elements with 2 nodes.*

### **1.2** **Material properties**

*Each discrete element has a stiffness:  $K = 1.000 \text{ NR /m}$*

### **1.3** **Boundary conditions and loadings**

*In  $x=0$*

*$dx = Dy = 0$*

*In  $x=L$*

*$Fx=10N$*

## **2** **Reference solution**

### **2.1** **Method of calculation used for the reference solution**

*Analytical solution: displacement for an element is given by:*

$$U_x = F/Kx$$

*Thus for N springs:  $U_x = N F/Kx$*

## **2.2**

### **Results of reference**

*Values of displacement for  $x=L/2$  and  $X=L$ , as well as effort in the elements (constant):*

$$U(L/2) = 0.05 \text{ m}, U(L) = 0.1 \text{ m}, N=10N$$

## **2.3**

### **Uncertainty on the solution**

*Exact analytical solution.*

***Problem of reference***

***1.1 Geometry***

***A system of 3 bars out of U:***

**B**

***With***

**y**

**D**  
**X**

**C**

*The surface of the cross sections is worth  $A=1\text{m}^2$ . The length of each of the 3 bars is worth  $L=10\text{m}$ .*

**1.2**

*Material properties*

*$E = 2.1011\text{ Pa}$  for the 3 bars.*

*$\text{Rho}=8000\text{ kg/m}^3$  only for the bar CD. For the 2 other bars,  $\text{Rho}=0$ .*

**1.3**

*Boundary conditions and loadings*

*Embedding in A and B.*

*In order to avoid the movements of rigid body,  $DZ=0$  for all the nodes, and  $DX=0$  out of C and D.*

*1 only loading is applied: gravity, with  $g=2\text{m/s}^2$ , in the direction  $(0.866, -0.5, 0)$ , which*

*to  $G = 10\text{m/s}^2$  is equivalent, in direction Y.*

**2**

*Reference solution*

**2.1**

*Method of calculation used for the reference solution*

*· Analytical Solution:*

*Normal effort in each bar AC and data base:  $N=\text{Rho}*L*A*g/2$*

*Uy displacement out of C and D:  $Uy=NL/ES$*

**2.2**

*Results of reference*

*· Normal Effort in bars AC and data base:  $N= 4.105\text{ NR}$*

*· displacements out of C and D:  $Uy=2\ 10^{-5}\text{m}$*

## ***Summary of the results***

***This test, very simple, makes it possible simultaneously to check the correct operation of gravity in elements of bar, which is checked by the perfect coincidence of the results with the solution analytical. It was introduced following the discovery D`an anomaly on gravity into the bars, and allows to validate the correction.***

**SSLL111 - Static response of a beam concrete  
armed (section in T) with linear behavior**

**Summary:**

**The problem consists in analyzing the response of a concrete beam reinforced via a modeling multifibre beam. This test corresponds to a static analysis of a beam having a linear behavior. Three successive loading cases are tested: a specific force, the actual weight and a rise in temperature. For the first loading case, two grids of the section, one coarse and the other finer are tested.**

**Reference solution**

**Calculations of reference are carried out starting from a simple elastic design in RdM.**

**2.1 Center**

**rubber band**

**In pure bending, for an elastic behavior, the neutral axis passes by the elastic center (barycentre of the sections balanced by the modules of materials):**

**$C \text{ such as } E \int CM dS = 0$**

**S**

**One determines initially the position of the centres of gravity of the concrete only G and steel only G by**

**B**

**has**

**report/ratio at the point O.**

**$y = 0,125 \times 0,3 \times 0,05 - 0,125 \times 0,2 \times 0,05 = 1,38888 \cdot 10^{-2} \text{ m}$**

**G B**

**$0,2 \times 0,05 + 0,1 \times 0,2 + 0,3 \times 0,05$**

$$y = 0,125 \times 3 - 0,125 \times 4 = -1,78571 \cdot 10^{-2} \text{ m}$$

**G has**

**3+ 4**

$$Z = Z = 0 \text{ m}$$

**Ga**

**GB**

*One can then determine the position compared to O of the elastic center C.*

$$EaSa OGa + EbSb$$

**B**

**OG**

$$OC =$$

$$EaSa + EbSb$$

*The concrete S section is 0,045 m<sup>2</sup> and the section of steel S is 7.104 m<sup>2</sup>. The Young modulus of B has*

*concrete is 2.1010 MPa and that of steel 21.1010 MPa. One thus has*

$$y = 2 \times 0,045 \times 1,38888 - 21 \times 7.10^{-4} \times 1,78571 = 0,94317 \cdot 10^{-2} \text{ m}$$

**C**

$$2 \times 0,045 + 21 \times 7.10^{-4}$$

$$Z = 0 \text{ m}$$

**C**

## **2.2 Moments**

**quadratic**

*The quadratic moments of the rectangular concrete sections are calculated by the formula following:*

**3**

**bh**

**2**

$$+ B \times H \times D$$

**12**

*Where, B represents the width, H the height and D the distance from the centre of gravity of the section by report/ratio with the axis for which one calculates the moment.*

*One then obtains the quadratic moment of the concrete section compared to axis Z passing by center elastic:*

**3**

4/8

*Inertias of steels are calculated by the following formula:*

$$4 + S \times d^2 \quad S \times d^2$$

$$64$$

*Where, represents the diameter of steel, S the steel section and D the distance from the centre of gravity from section compared to the axis for which one calculates the moment. The diameter of steels being small, one neglect the first term.*

*One then obtains the quadratic moment of the steel sections compared to axis Z passing by the center rubber band:*

$$3.10^{-4} \times (0,125 - 0,94317.10^{-2})^2 + 4.10^{-4} \times (0,125 + 0,94317.10^{-2})^2 = 0,1124.10^{-4} \text{ m}^4$$

*For the complete section of the beam, the quadratic moment balanced by the Young moduli of materials is:*

$$I.E.(\text{internal excitation}) = 2.1010 \times 0,4547.10^{-3} + 21.1010 \times 0,1124.10^{-4} = 11,4544.106 \text{ Pa.m}^4$$

**2.3****Loading case 1**

*In the case of load 1 (loading concentrated in the middle of the beam), the arrow is calculated by formulate following RDM:*

*F L 3*

×

$F =$

$48EI$

What gives the arrow:

$F =$

$10000 \times 53$

$= 2,2735.10^{-3} m$

$48 \times 11,4544.10^6$

One can also calculate the following generalized efforts:

$F$

· the shearing action at the beginning of the beam (left left) is worth

$= 5000 NR,$

$2$

$F \times L$

· the bending moment in the middle of the beam is worth:

$= 1,25.10^4 N.m.$

$4$

## 2.4

### Loading case 2

In the case of load 2 (actual weight of the beam), the arrow is calculated by the formula of RDM following:

$F = 5 \times p \times l^4$

384 I.E.(internal excitation)

where  $p$  is the linear load due to the weight of materials:

$p = G (S + S) = 9,8 \times (2800 \times 7.10^{-4} + 2400 \times 0,045) = 1111,9 NR .m^{-1}$

has has

$B B$

What gives the arrow:

$F = 5 \times 1111,9 \times 54 = 7,9.10^{-4} m$

$384 \times 11,4544.10^6$

## **2.5**

### ***Loading case 3***

*In the case of load 3 (homogeneous rise in temperature), the beam being isostatic and them dilation coefficients of the concrete and steel being identical, the solution is simple:*

*The generalized constraints and efforts are null.*

*The lengthening of the beam is:  $L = \alpha L \times T$*

*What gives with the values of our case:*

$$L = 10^{-5} \times 5 \times 100 = 5 \cdot 10^{-3} \text{ m}$$

## **3 Modeling**

### **3.1**

#### ***Characteristics of modeling***

***Longitudinal grid of the beam:***

***We have 3 nodes and two elements (POU\_D\_EM).***

***With***

***C***

***B***

***The concrete part of the cross section of the beam is with a grid (AFFE\_SECT) while steels are given directly in the form of 4 specific fibres in AFFE\_CARA\_ELEM (AFFE\_PONCT).***

***Two grids of the concrete part are tested in the case of load 1. The fine grid consists of 120 fibres and the coarse grid consists of 16 fibres:***

**Note:**

*The problem being 2D, only one fibre in the width could seem sufficient (multi-layer), but that would result in having null terms in the matrix of rigidity (the own inertia of fibres not being taken into account) and with an error at the time of the resolution of system of equations.*

(2)

**1) Calculations are carried out without taking into account the own inertia of each fibre. Results show that it is not nevertheless very useful to hold account of it because the difference between one coarse grid and a fine grid is not obvious.**

**The grid of the section does not need to be very fine to have precise results (in elasticity).**

**2) Option EFGE\_NOEU\_DEPL used to calculate the efforts generalized with the nodes does one average of the generalized efforts of all the elements connected to the node. In our case, we have 2 superimposed elements of beam (for the concrete, for steel), the efforts calculated are thus divided by 2.**

**If one adds the values with efforts by element (EFGE\_ELNO\_DEPL) of the element concrete and with the element steel, one finds the theoretical values well.**

**Note:**

**If one makes a calculation of arrow by taking O (middle height) like reference axis to the place elastic center (COOR\_AXE\_POUTRE), the relative error on the arrow is 0,2% here (but its center elastic is practically with middle height (see 1.2.1)).**

***Handbook of Validation***

**V3.01 booklet: Linear statics of the linear structures**

**Document: V3.01.114**

**FORMA06 - TP beam of the formation post  
treatment**

**Summary:**

**The objective of this T.P. is to use the possibilities of POSTPROCESSING available in Code\_Aster in the case of a modeling of the BEAMS type.**

**It is about a gantry with side connections made up of a linear elastic material. In this T.P, one is interested**

**with the following operators of postprocessing:**

- operators allowing to define groups of entities of the grid type: *DEFI\_GROUP* (definition and handling of groups of nodes and meshes),**
- total operators allowing to enrich the concepts results: *CALC\_ELEM* for the calculation of fields with the elements and *CALC\_NO* for the calculation of the fields to the nodes,**
- impressions: *IMPR\_RESU* (impression of the results to the formats *RESULT*, *IDEAS*, *GIBI*),**
- localised examinations: *POST\_RELEVE\_T* to raise of values on lines and calculation of derived quantity,**
- layout of curve: *IMPR\_COURBE* to visualize the evolution of a size according to space.**

## **Summary of the results**

*The results obtained with Code\_Aster are in concord with the reference solution.*

*The recovery in this case test of the command file of the TP on the post treatment of the beams allows to make sure that this file remains in agreement with the evolutions of syntax of the code.*

***SSSL116 - Lattice reinforced 3D***

***Summary:***

***This test relates to the study of a lattice made up of hurled beams, in linear static analysis.***

***The lattice is modelled with elements linear (SEG2) and subjected to a specific loading and the effect of gravity.***

***There is a modeling with a first geometry, then a modeling with bars of reinforcement.***

***This test is an example with didactic aiming since it shows the construction of the solution by finite elements rather to use MECA\_STATIQUE directly.***

## **Summary:**

***This test be resulting from the validation independent of version 4 of the models of doors.***

***This test allows the checking of calculations of beam right-hand sides in the linear static field. (a modeling with elements of beams POU\_D\_E, right beam of EULER).***

***One calculates simultaneously 3 beams of the different sections: section rings, right-angled, and general. These beams are subjected to efforts specific or distributed.***

***The values tested are displacements and rotations, the efforts generalized, and the constraints.***

y

*We calculate then rotation starting from the law of behavior = E I (X*

y

).

 $X$  $M(X$  $y$ 

)

We thus have  $(X) =$

 $dx + C$  $E I (X$  $y$ 

)

3

with such as  $(0) = 0$ .

 $W$ 

The arrow  $W(X)$  is given starting from the relation of Euler:  $y = -$ .

 $X$ 

We calculate  $W(X)$  by integration of  $y(X)$ :

 $W(X) = -$  $(X) + C$  $y$ 

4

with  $C4$  such as  $W()$

 $0 = 0$ .

The analytical expressions of  $y(X)$  and  $W(X)$  are not retranscribed here because they are much too much heavy. They were calculated, like the preceding ones, by the formal computation software **MATHEMATICA**.

***Summary of the results***

***The results obtained confirm that elements POU\_D\_E with variable section present a good degree of reliability.***

***For the circular section, the results all are exact with the nodes (one finds the properties of the element with constant section) except for the efforts distributed where the effect of the smoothness of discretization fact of feeling.***

***For a rectangular section and a general section, it is necessary to discretize finely to have one correct solution.***

*5*

*Summary of the results*

*The results are very close to the analytical solution (variation: 0,4% per 10 elements). This variation is function of the smoothness of discretization being given assumptions used for rigidity geometrical (cf [R3.08.01]). This thus validates this type of loading for the buckling of Euler.*

## **Summary**

***The applicability of this test is the analysis of stability of the structures. The studied structure is an arch bent by moments applied at the two ends; it is modelled by elements of beams right-hand sides. The goal is to calculate the breaking values of the moments.***

***The interest of this test lies in the following aspects:***

- calculation of a geometrical matrix of rigidity for elements POU\_D\_E.***
- test of modal methods MODE\_ITER\_SIMULT and MODE\_ITER\_INV of stability***
- presence of close eigenvalues***

***The calculated clean loads are compared with values obtained analytically for a model of beam of Euler-Bernoulli.***

***In this test, one also validates the RAYLEIGH option of order MODE\_ITER\_INV.***

## ***1.3***

***Boundary conditions and loading***

***The beam Bi-is supported. One prevents the torsion of the section at ends A and B. to respect the assumptions of the ideal model taken as reference, it is important that the moment is constant and that the normal effort is null along the beam. This is why free it is left displacement U according to X at the point B. the boundary conditions are:***

***At point a:  $U = v = W = 0; Y = 0$***

***At point b:  $v = W = 0; X = 0$***

***The initial state of stress which makes it possible to carry out the analysis of stability is obtained by imposing one bending moment around axis Z:***

***At points A and b:  $M = 1 Nm$***

### **Summary of the results**

*The methods of Sorensen and the iterations opposite give identical and satisfactory results since the maximum change with the analytical solution is lower than 4.5%. On recalls than the solution analytical takes into account the curve of the structure.*

*Elements MEPOUCT could not be used in this test because the calculation of the matrix of rigidity geometrical is not available for this type of element.*

***SLL501 - Piping VVP.  
Comparison Aster-SYSPIPE***

***Summary:***

***This test makes it possible to check the elements of beam for the calculation of line of piping real, in particular them elements of curved beam POU\_C\_T. Calculation is static, elastic, linear.***

***The reference solution is numerical (code SYSPIPE).

### ***Characteristics of the sections:***

.

*Right parts:*

- $R = 406.4 \text{ mm}$ ,  $EP = 32. \text{mm}$
- Mesh 1 (pipe Steam Generator),  $R = 410. \text{mm}$ ,  $EP = 38. \text{mm}$ ;
- Mesh 49 (exit Br),  $R = 444.4 \text{mm}$ ,  $EP = 70. \text{mm}$ ;

.

*Elbows:*

- meshes: (M2 M6 M18 M21 M26 M30 M35 M39 M44 M46):  $R = 406.4 \text{mm}$ ;  $EP = 34. \text{mm}$ ;
- Coefficient of flexibility for all the elbows,  $c_{flex} = 6.032$ ;
- Rays of bending of the elbows:  $1220 \text{mm}$

## **1.2**

### ***Material properties***

$E = 1.8604E+5 \text{ MPa}$  (with  $287^\circ\text{C}$ )

$\alpha = 12.81e-6 \text{ } ^\circ\text{C}^{-1}$ ; = 0.3

## **1.3**

### ***Boundary conditions and loadings***

.

*Displacement imposed on node 50 (mesh, side Steam Generator)*

$dx = 46.466 \text{mm}$ ;

$Dy = -30.494 \text{mm}$ ;

$dz = 76. \text{mm}$ ;

null rotations:  $drx = dry = drz = 0$

.

*The N1 node is embedded:*

$dx = dy = dz = drx = dry = drz = 0$

ma\_123  
S\_123

The macr\_elem\_stat S\_123 is defined starting from substructures ABCD, DCEF and FEGH. It macr\_elem\_stat is condensed on the nodes of AB and GH.

The grid mag0 is defined by the macr\_elem\_stat S\_123.

The final grid mag (level 0) is defined by the grid mag0 which one assembles (ASSE\_MAILLAGE) with the initial grid my to recover the meshes of IJBA.

The resolution is then made on this final grid, then one calculates displacements inside macr\_elem\_stat using operator DEPL\_INTERNE.

### **Summary of the results**

The precision of the results obtained (error <sup>2</sup> 105) is natural because the static under-structuring is one “exact” method (in infinite numerical precision).

***Document: V3.02.101***

***SSLP101 - Rate of refund of energy  
in plane constraints***

***Summary:***

***It is about a test of breaking process in statics for a two-dimensional problem. One is considered plate fissured in plane constraints, the functionalities tested are:***

.  
*the rate of refund of energy  $G$ ,*

.  
*the rate of refund of energy calculated starting from the calculation of the coefficients of constraints  $K1$  and  $K2$ .*

*The interest of the test is to compare the traditional value of  $G$  and the value of  $G$  (IRWIN) obtained starting from  $K1$  and  $K2$ . It also makes it possible to test the invariance of calculation compared to the crowns of integration.*

*This test contains 3 different modelings: the modeling A which treated calculation of the Integral of Rice is not more supported since Version 3.*

**Results of references**

The result for  $J$  in card ECA (Code CASTEM 2000) is  $J = 0.390$  kgf/mm (not indication on contours).

The results resulting from WILSON and YU vary for five different contours:

1  
0.392  
2  
0.362  
3  
0.369  
4  
0.361  
5  
0.371

**Summary of the results**

The variation of the results of G with the values of 5 data in WILSON and YU is less than 2% except for smallest contour where the variation reaches 9%. No indication of contour is mentioned for the single value indicated in card CASTEM, this value is very close to that of WILSON and YU for smallest contour. The invariance of G following the crown is excellent for Aster calculation. Let us note the difference in modeling between this test where deformations directly are imposed initial and results of reference where these deformations are induced by an imposed temperature. The grid corresponds to this case test is also appreciably finer than that used for results of reference.

## **constraints $KI$ and $KII$ for a circular plate fissured in linear elasticity**

### **Summary**

It is about a test of breaking process in static linear elasticity for a two-dimensional problem. One consider a circular plate fissured (with a tilted crack of 30 degrees compared to the axis of X-coordinates) for which one calculates:

- coefficients of intensity of constraints  $KI$  and  $KII$ ,
- the rate of refund of energy  $G$  starting from the formula of IRWIN.

The interest of the test is to know the analytical solution which gives the coefficients of intensity of constraints and to have a tilted crack.

This test includes/understands a modeling which treats successively the plane strains and the plane stresses (elements of continuous mediums).

The numerical results do not deviate more than 1 to 2% from the values of reference.

#### 4.2 Remarks

(1 - 2) 2 2

The formula of IRWIN gives:

$G =$   
 $(K + K$   
 $I$   
 $II)$   
in plane deformations  
 $E$

1  
2  
2  
and

$G =$   
 $(K + K$   
 $I$   
 $II)$   
in plane constraints  
 $E$

Calculations are carried out with a crown of lower integration of ray 10.0 and ray superior 20.0.

## ***SSLP105 - Excavation of a circular tunnel in a linear elastic solid mass***

### ***Summary:***

***This test constitutes an example of implementation of a total methodology for simulation two-dimensional of the digging and the supporting of a circular gallery in an underground solid mass with Code\_Aster.***

***To validate the step on the basis of simple analytical solution, one is brought to make assumptions restrictive on the geometry of the problem, the behavior of materials (elastic linear) and the field of constraint initial (isotropic). The reference solution is given by the method known as “convergence containment”, traditional for this type of modeling 2D.***

### 1.3

#### *Initial conditions, boundary conditions and loadings*

*The constraints in the solid mass are supposed initially isotropic ( $xx = yy = zz = 0$ ). method used to simulate the excavation and the installation of supporting is the method known as “convergence-containment” presented for example in [bib1] and [bib2].*

*The guiding principle rests on a reduction in the nodal reactions generated at the edge of the future one gallery by the initial state of stresses. This operation is indicated by name “déconfinement”. When déconfinement the value reached which corresponds to the conditions of building site which one wishes to model, one carries out the simulation of the installation of concrete supporting at the edge of the gallery.*

### **Summary of the results**

*This test, based on a solution of hurled plate, is treated in 2D (forced plane) in order to validate the loading of edge (key word FORCE\_CONTOUR). The solution obtained is close to the solution analytical (0.4% of difference on displacements) and thus this type of modeling validates.*

**Handbook of Validation**

**V3.02 booklet: Linear statics of the plane systems**

**V3.02.304 document**

**SSLP304 - Orthotropic square plate in traction  
uniaxial out of the axes of orthotropism**

**Summary:**

**This test represents the static calculation of a square plate, out of orthotropic elastic material, of which axes orthotropic are tilted 30 degrees compared to the basic edge, subjected to a uniaxial traction. It allows to validate the good taking into account of orthotropic elastic materials and the change of associated reference mark.**

**4 modelings are used: C\_PLAN with meshes QUAD8 and TRIA6, in a first reference mark, C\_PLAN in a second reference mark, COQUE\_3D with meshes QUAD9 and TRIA7, in small displacements and COQUE\_3D in great displacements. Displacements and the constraints obtained are compared with a reference solution analytical.**

*The first two modelings of this test result from the validation independent of version 3 of Code\_Aster (linear static batch).*

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**Analytical solution, obtained with the assumption of uniaxiality of the constraints:**

**(X, y)**

**xx**

**= F**

**(X, y)**

**X**

**xy**

**=**

**(X, y)**

**yy**

**=**

**(X, y)**

**zz**

**= 0**

*maybe in the reference mark (A, L, T):*

$$(X, y) = c2F, (X, y) = s2F$$

$$(X, y) = -csF$$

**LL**

**X**

**TT**

**X**

**LT**

**X**

*By the orthotropic law of behavior elastic, by using conventions of Code\_Aster in what relate to NU\_LT, (cf document of use of order DEFI\_MATERIAU [§3.5.2]), one obtains directly (see for example [bib1]):*

$$(X, y) Fx$$

=

xy

$$, (X, y) = -$$

F, 2

**X**

$$(X, y) =$$

**F**

**xx**

**E**

***6 Modeling***

***D***

***6.1***

***Characteristics of modeling***

***Modeling COQUE\_3D in great displacements. The plate is parallel to the total axes, i.e. total axis X is colinéaire with axis X. It is thus the axis of orthotropism L which is to be directed (using the MASSIVE key word of AFFE\_CARA\_ELEM). The grid is identical to that of modeling B.***

unlimited plane field***

***Summary:***

***This test results from the validation independent of version 3 in breaking process.***

***It is about a two-dimensional test in statics (plane strains or stresses) which aims at checking of G and KI under loading by pressure distributed not uniform on the lips, in unlimited medium. One also check the nullity of KII with option CALC\_K\_G.***

***The behavior of the structure is elastic linear isotropic.***

***The case test includes/understands only one plane modeling 2D in which one studies the influence of the parameter C intervening in the loading.***

## **4.2 Remarks**

***Constant 2,4048... is first zero of the function of Bessel J.***

0

*Crown 0 (surrounding the bottom of crack consists of triangles) gives poor results compared to the other crowns.*

*The relative variations maxima between crowns 1,2 and 3 for G and KI are given below for various loadings.*

*Loading 1 Loading 2 Loading 3 Loading 4 Loading 5*

*Variation on G*

*0,03%*

*0,03% 0,03% 0,03% 0,03%*

*Variation on KI 0,002% 0,002% 0,002% 0,002% 0,002%*

*The variations on G and KI are negligible.*

*Comment on the results of the loading n°5 with  $C = 2,4048\dots$*

*The loading n°5 can be compared in order of magnitude with the loading n°1. Indeed, the amplitude loading n°5 is worth 1 and its resultant is worth 1,14 to compare with the unit constant value loading n°1.*

*The absolute deviation for the loading n°1 and crowns it n°1 is of:*

- 2,53E-5 for G*
- 8,34E-3 for KI*

*For the loading n°5, the Aster values which are compared with a null value of reference are:*

- 3,98E-8 for G*
- 4,72E-3 for KI*

*The order of magnitude on the absolute deviations is similar for the two loadings. One can thus regard as correct the Aster results.*

5

*Summary of the results*

*Except for the results obtained on crown 0, calculations of K and G are very close to exact theoretical solution. Indeed, the variations are always lower than 1,2% for the calculation of G and*

*lower than 0,6% for the calculation of KI.*

subjected to uniform traction*

## **Summary:**

***This test results from the validation independent of version 3 in breaking process.***

***It is about a two-dimensional test in statics with Bi-material in the presence of an internal crack of interface oblique.***

***The behavior of the structure (Bi-material) is elastic linear isotropic.***

***The case test includes/understands four modelings in plane constraints in which the influence of the slope of the crack is studied (4 cases).***

**1**

***Problem of reference***

**1.1 Geometry**

***One considers 4 values of the angle = 15°, 30°, 45° and 60°.***

***Other dimensions are selected such as  $H = 2W = 4a$ .***

***The value of A is worth 1.E-3 Mr.***

**1.2**

## ***Properties of materials***

### ***Material n° 1***

***Rubber band, linear, isotropic, Young modulus  $E1 = 2E+12$  Pa and Poisson's ratio  $1 = 0,3$ .***

### ***Material n° 2***

***Rubber band, linear, isotropic, Young modulus  $E2 = 2E+11$  Pa and Poisson's ratio  $2 = 0,3$ .***

## ***1.3***

### ***Boundary conditions and loading***

***· The loading being autoéquilibré, one is satisfied to block the 3 rigid modes:***

***$UX = UY = 0$  with the left lower corner of the complete model.***

***$UY = 0$  with the corner lower right of the complete model.***

***· On the lower edge, we impose  $UY = 0$***

***· Chargement: uniform tension  $yy = 0$  on the higher edge:***

***The value of 0 is worth 100MPa.***

## ***2***

### ***Reference solution***

#### ***2.1***

***Method of calculation used for the reference solution***

*Method of the elements of border, with quadratic elements [bib1].*

*The calculation of KI and KII is carried out by an integral of contour (integral M [bib2]) in which the constraints and displacements calculated in the part intervene, as well as the constraints and displacements deduced from analytically definite asymptotic solutions, in which KI and KII are alternatively null. The calculation of K is also carried out by the method of virtual extension, as comparison.*

## **7.2 Remarks**

***To obtain G on the bottom of crack, one calculates the rate of refund of energy using the relation between G and K<sub>j</sub> [bib3]:***

=  
 = **2 076923**  
 ,  
 1  
 2  
 $\mu = 7\ 6923$   
 ,  
 $E + 11$   
 1  
 $\mu = 7\ 6923$   
 ,  
 $E + 10$   
 2  
 = **-9 37742**  
 ,  
 $E - 2$   
 = **2 524488**  
 ,  
 $E - 12$   
 $G = (2$   
 2  
 $K + K$   
 $I$   
 $II)$

## 8 *Summary of the results*

*The calculation of G is not precise on the first crown in all the cases of slope of the crack. With regard to the other crowns, the variations are about 0,4%. In the case of slope = 60° the variation exceeds 1%. As a whole the results are satisfactory for G.*

*The calculation of KI and KII is not available for a crack located at the interface of a bimatériau.*

*One allots an unspecified value to the slope, = 37 degrees.*

*One chooses has = 1.E-3 Mr.*

## **1.2**

### **Properties of material**

*The material is elastic linear isotropic, of Young E and Poisson's ratio modulus.*

*E = 2.E11 Pa, = 0.3.*

*Assumption of the plane constraints*

## **1.3**

### **Boundary conditions and loadings**

.

*Arbitrary limits of the field with a grid:*

*- xmax X xmax with xmax = 10a*

*- ymax y ymax with ymax = 20a*

.

*Boundary conditions:*

*In order to block the 3 plane rigid modes exclusively.*

*UX = UY = 0 with the left lower corner of the complete model.*

*UY = 0 with the corner lower right of the complete model.*

*On the lower edge, we impose UY = 0*

.

*Loading: uniform tension yy = 0 on the higher edge:*

*The value of 0 is worth 100MPa, in plane constraints.*

**Author (S):**

**J.M.PROIX, I. CORMEAU, E. LECLERE Key**

**:**

**V3.02.313-A Page:**

**10/10**

**7**

**Summary of the results**

**With this choice of the limits of the field of calculation, we obtain variations of about 1% on coefficients KI and KII, and on the rate of refund of energy G.**

**With regard to method POST\_K1\_K2\_K3, the results are further away from the reference with a standard grid (from 1% to 30% of variation), on the other hand, with a grid of the type Barsoum (nodes mediums with the quarter on the sides), recommended for this type of method, the differences are included/understood between 3% and +1.2%, which is relatively precise.**

***Document: V3.03.009***

***SSLS09 - Thin cylinder under actual weight***

***Summary:***

***This test from guide VPCS (SSLS 09/89) aims to test a voluminal loading (here the weight clean), in axisymmetric analysis, by using key word FORCE\_INTERNE.***

***One will use for that the two orders: AFFE\_CHAR\_MECA (modeling A) and AFFE\_CHAR\_MECA\_F (modeling B).***

***Modeling C tests the incompressible elements by using the key word GRAVITY on a loading equivalent.***

***Summary of the results***

***The use of a function for the definition of a constant density of volume charge is valid: results are identical, whether one uses one or the other of 2 orders AFFE\_CHAR\_MECA or AFFE\_CHAR\_MECA\_F. An equivalent loading gravity gives the same results.***

***Moreover, the incompressible elements give the same results (modeling C).***

### **Summary of the results**

With regard to the elements:

· DKT:

-

Suitable solution for a fine network.

-

To supplement later on:

-

by a less fine grid,

-

by an analysis of the constraints,

-

by 4 modelings (DKQ, DST, DSQ, Q4G).

· MEC3QU9H: very good solution obtained with a relatively coarse network.

· MEC3TR7H: to arrive at a suitable solution, that requires a fine grid, compared with that for element MEC3QU9H. In the same way compared with element DKT, the number of nodes total is much more important.

### **V3.03 booklet: Linear statics of the plates and hulls**

**Document: V3.03.027**

#### **SSLS27 - Bored or bent thin section**

##### **Summary:**

The test, taken again guide VPCS, makes it possible to check the behavior of an embedded plane plate subjected to sound

load with two nodal forces of the same sign (inflection) or of opposite sign (torsion).

The first loading constitutes an extension of the initial test for which a reference solution is given in [bib3]. Only one modeling in element DKT.

### **Reference solution**

#### **2.1**

##### **Method of calculation used for the reference solution**

· Opposite Forces perpendicular to the plate [bib1], [bib2]

The reference solution is that given in card SSLS27/89 of guide VPCS:

Displacement of the point C:  $W = 35.37 \cdot 10^{-7}$  m

· Of the same Forces feel perpendicular to the plate [bib3]

The formulation in beam of Euler gives a solution approached for a Poisson's ratio

.

$F$

3

Displacement of all the nodes on the side BC:  $W =$

$2 L$

6th  $I_z$

#### **2.2**

##### **Results of reference**

Displacement of the points B, C and E.

#### **2.3**

##### **Uncertainty on the solution**

## 1.2 *Material properties*

**$E = 1 \text{ Pa}$**   
 **$\nu = 0.3$**   
 **$\rho = 1 \text{ kg/m}^3$**

## 1.3 *Boundary conditions and loadings*

*Embedding on the edge of the plate:*  
*in all the points  $P$  such as  $COp = R$ :  $U = v = W = 0, X = y = Z = 0$ .*

**FORCE\_COQUE**  
*Uniform pressure*  
 **$P = 1 \text{ N/m}^2$**   
**FORCE\_COQUE**  
*Charge distributed normal*

**$F3 = 1 \text{ N/m}^2$**   
**GRAVITY**  
 **$G = 10 \text{ m/s}^2$  according to  $Z$  from where**  
 **$FZ = WP = 1 \text{ N/m}^2$**

*These three loadings lead to the same solution.*

**V3.03.100-C Page:**

**3/24**

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**Two reference solutions are usable, for the calculation of the deformation:**

**.**

**the theory of LOVE-KIRCHHOFF, usually used for the plates known as “thin”, that one will retain for modelings A, B, C, D, E and I,**

**.**

**the theory of MINDLIN-REISSNER, including the effects of shearing for the plates known as “thick”, that one will retain for modelings F, G, H and J.**

**In any distant point of R of the center of the plate (R R), the arrow is expressed:**

**4**

**2**

**2**

**3**

**(**

**P R**

**R**

**R**

**E T**

**W R) = -**

**1-**

**1-**

+ *with D =*

**64D**

**R2**

**R2**

(

**12 1 - 2**

)

**16 T 2 1**

*with = 0 (- KIRCHHOFF COILS) or =*

**(REISSNER.**

)

**5 R 1 -**

*For the calculation of the moments the two theories lead to the same expressions:*

**P R2**

**R 2**

**P R2**

**R 2**

**M (R)**

**(3 )**

**(1) M (R) =**

(

**1+ 3)**

**(1 )**

**rr**

**=**

**+**

**16**

**R - +**

**16**

**R**

**- +**

*In the center of the plate:*

**4**

**4**

**(**

**P R**

**P R**

**W)**

**0**

**= -**

**(- KIRCHHOFF COILS) or (**

**W)**

**0**

**=**

**-**

**(I+) (REISSNER)**

**64D**

**64D**

**P R2**

**M ()**

**0**

**= M ()**

**0**

**= -**

**(I+**

**)**

**rr**

**16**

**Note:**

*Code\_Aster calculates the moments with the nodes of each finite element in the reference mark of reference defined by the external normal and the reference axes defined on the hull (see AFFE\_CARA\_ELEM [U4.24.01]).*

*The value of moment Mxx (or Myy) in a node pertaining to several finite elements can to be regarded as being the average of the computed values on the elements which have this node jointly. This average can be obtained by procedure POST\_RELEVE [U4.74.03].*

*For each node, one a:  $(M + M) = (M + M) = S_m$*

**rr**

**xx**

**yy**

*for the point O*

*SSLS101 - Plate circular posed subjected  
with a uniform pressure*

**Summary:**

*One treats the case of a circular plate posed on the edge in linear elasticity under 3 loadings (weight clean, pressure, effort distributed constant) which gives the same deformation.*

*The first two modelings make it possible to evaluate the influence of the grid.*

*The test gathers 9 modelings (model Coils-Kirchhoff, Mindlin-Reissner and COQUE\_3D and SHB8).*

**V3.03 booklet: Linear statics of the hulls and the plates**

**Document: V3.03.104**

**SSLS104 - Cylindrical hull pinch**

**with diaphragm**

**Summary:**

**One treats in linear elasticity the case of a cylinder formed by two circular funds at the two ends and gripped**

**with semi-length.**

**This makes it possible to treat the modes of deformation inextensionnels and a complex membrane behavior**

**had with the diaphragms.**

**The value tested is the arrow at the point of application of the force.**

**Three modelings: DKT, COQUE\_3D QUAD9 and COQUE\_3D TRIA7.**

displacement v

**8.2 Remarks**

For a grid with 500 meshes TRIA7 and 1071 nodes (cutting 10 on AD and BC, 25 on AB and Cd.), one obtains a displacement v at the point C of 1.7723 105. The relative error on displacement v in C is then 2.88%. The results with this element for light grids is thus not very good and improves relatively little with an increase of the number of meshes.

### **Summary of the results**

With regard to the elements:

**DKT:**

The result is better with a finer grid (1366 nodes) which leads to an error  $< 1.5\%$ .

**MEC3QU9H:**

The result is acceptable with relatively few elements (compared with DKT). While increasing appreciably the number of elements (60 instead of 32), the error is  $< 1.3\%$ .

**MEC3TR7H:**

Result little satisfying even with a fine grid leading to a great total number of nodes for MEC3TR7H (777 for MEC3TR7H to be compared with 209 for DKT and 121 for MEC3QU9H). To arrive at an error lower than 2.9%, that requires a very great number of nodes (1071). It seems recognized that this element is worse than MEC3QU9H.

## **8.2 Notice**

*For this modeling, convergence is relatively slower than for the MEC3QU9H, it is necessary in effect 1200 elements to obtain a relative error of about 1%. But time CPU is not crippling (12s). This is undoubtedly due to the choice of the law of behavior specific to the element SHB8: law of plane constraints, and nonnull rigidity in the direction of the normal to the element. If one chose a law of elasticity in plane constraints, without modification, one one would obtain then correct solution (0,2% of variation) as of the 1st case (300 elements). But this law would be then unsuited for other tests, such that of the sphere under pressure (SSLS123).*

## 9

### *Summary of the results*

*Severe test which requires a fine grid, in particular for element DKT. Results with the element MEC3TR7H were not retained as test because it is necessary to have many elements (1801) and thus a time of convergence much longer to obtain correct values by report/ratio with other modelings (> 500 S for a relative error of about 4%).*

*For element SHB8, convergence is relatively slower than for the MEC3QU9H, it is necessary in effect 1200 elements to obtain a relative error of about 1%. But time CPU is not crippling (12s).*

*Results in conformity with the reference solution.*

***SSLS107 - Subjected cylindrical panel***  
***with its own weight***

***Summary:***

***This test makes it possible to validate two finite elements of thick hull in linear elasticity. Modeling A tests it quadrangle, modeling B tests the triangle associated with the formulation. This problem of cylindrical panel under actual weight is a traditional test of hull.***

***The results of reference are analytical solutions.***

***One will note the good results obtained with the quadrangle and the results much worse obtained with triangle.***

### **Summary of the results**

*Element MEC3QU9H makes it possible to obtain a good solution with a coarse grid, while element MEC3TR7H requires a very fine grid to reach a satisfactory precision.*

*It is noted that the reference solution is the analytical solution obtained starting from the theory of “deep” hulls. The 2 elements of hull converge towards this solution and not towards the theory “not very deep” hulls.*

***Handbook of Validation  
V3.03 booklet: Linear statics of the plates and hulls  
Document: V3.03.108***

***SSLS108 - Helicoid hull under load  
concentrated***

***Summary:***

***This test in linear elasticity is very severe from its geometry (left hull). Two first modelings correspond one to the element of QUAD of modeling COQUE\_3D (MEC3QU9H) and the other with element TRI7 of modeling COQUE\_3D (MEC3TR7H). The two following ones relate to modeling SHB8.***

***The values of reference are computation results provided in the literature and the comparison calculation/reference relates to displacement in a point of the structure. One notes variations compared to reference lower than 0.15% for element MEC3QU9H and lower than 0.4% for element MEC3TR7H. For modelings SHB8, the stupid maximum changes of 1.4% with 24 elements SHB8 (modeling C) and 0.3% with 96 SHB8 (modeling D).***

***SSLS109 - Plate in traction made up of three  
tablecloths of reinforcements (Model ROASTS)***

***Summary***

***This test quasi-static 2D forced plane enters within the framework of the validation of the finite elements in elasticity***

***linear. A plate made up of three tablecloths of reinforcements offset compared to the average layer is subjected to a uniaxial traction. The orientations of the reinforcements and the mechanical***

*characteristics are  
different for the three tablecloths.*

*The principal interest of this test is to validate in linear elasticity the model “ROASTS” which is in fact an element of thin section (DKT) with a offsetting compared to the average layer.*

*The results provided by the model “ROASTS” (modeling B) are identical to those obtained by modeling “DEFI\_COQU\_MULT” of Code\_Aster (modeling A).*

## **2.2**

### **Results of reference**

*Certain modes corresponding to the critical loads of the analytical solution are not symmetrical and cannot be collected with the conditions of symmetry for a quarter of plate. The Values of the critical loads obtained thus correspond to the first 3 symmetrical modes of buckling:*

- Mode 1 of the quarter of the plate = Mode 1 of all the plate*
- Mode 2 of the quarter of the plate = Mode 3 of all the plate*
- Mode 3 of the quarter of the plate = Mode 5 of all the plate*

## **2.3**

### **Summary of the results**

*The results obtained are very satisfactory for the two types of elements, QUAD9 and TRIA7, even if it is necessary to employ a greater number of elements triangles.*

***Handbook of Validation***  
***V3.03 booklet: Linear statics of the plates and hulls***  
***Document: V3.03.111***

***SSLS111 - Simple Excentremement of plate***

***Summary:***

***This test makes it possible to validate the offsetting of the simple plates (i.e it acts neither of multi-layer, nor of one homogenized behavior).***

***The reference is given by a first resolution where one models double-layered made up of 2 materials.***

***The validation is done in the second calculation where one models the 2 layers of the preceding model by 2 plates offset compared to the average plan of the first calculation.***

***Three modelings are used: DKT, DST (meshs QUAD4) DST (meshs TRIA3).***

**One applies a nodal force  $Fz = 1000$  to the A3 node.**

**In addition, one applies to the meshes M1, m2 and m3 (see drawing) the loading distributed (key word Force\_coque) according to:**

**$Fx = 200$  N/m<sup>2</sup>,  $Fy = 500$  N/m<sup>2</sup>,  $Fz = 500$  N/m<sup>2</sup>,  $MX = 100$  N/m,  $My = 40$  N/m**

**in the plan of the grid.**

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**Calculation with double-layered material is used as reference. Nonregression of the results obtained for it**

*the first calculation is checked.*

## **2.2**

### **Results of reference**

*They are consisted of the values of the field of displacement  $DX$ ,  $DY$ ,  $DZ$ ,  $DRX$ ,  $DRY$  at the point A3 (node N1 for ASTER) and at the point of co-ordinates (9,2,0).*

*One compares also the efforts with the A1 point.*

*In addition, the 4 smaller frequencies of the structure are calculated.*

## **2.3**

### **Uncertainty on the solution**

*Null since it is about the same calculation carried out by two different ways.*

**Summary of the results**

***With regard to modeling A (DKT) results obtained with two full-course hulls offset coincide perfectly with those obtained by a double-layered hull, as well in terms displacements, that generalized efforts or Eigen frequencies. This thus validates offsetting by hulls DKT.***

***On the other hand, modelings B and C, both with DST hulls, reveal one difference between the two ways of carrying out calculation. This one is lower than 1,5% with regard to displacements and frequencies, which remains reasonable.***

***On the other hand, there are variations on the efforts going up to 7% for modeling C (DST triangles) and 14% for modeling B (DST quadrangles).***

***This variation is not explained and one cannot know a priori if it is due to offsetting for DST modelings or with the multi-layer hulls DST.***

***SSLS113 - Offsetting of plates***  
***homogenized***

***Summary:***

***This test makes it possible to validate the offsetting of the plates having a behavior “ELAS\_COQUE”.***

***The reference is given by a first resolution where one models double-layered orthotropic not having one material symmetry compared to the average plan.***

***The validation is done in the second calculation where one models the behavior of the preceding plate by 2 offset full-course plates having a behavior “ELAS\_COQUE”.***

***uniform***

## **Summary:**

***One treats the case of a square plate tri-layers, simply supported and subjected to a uniform pressure. The skins consist of an orthotropic homogeneous material, as well as the heart (same axes of orthotropism).***

***The modules  $E$  and  $G$  of the heart are ten times weaker than those of the skins.***

***One calculates displacement in the center as well as the constraints with the lower and higher interfaces of skins.***

***The test gathers eight modelings: with regard to the four first, the results obtained are compared for triangular surface meshes then quadrangular, in two reference marks user different. Four last modelings make it possible to measure the sensitivity of the results the orientation triangular meshes in the two reference marks user.***

**8.2 Remarks**

***The values of reference of displacement to the point C are obtained by projecting displacement theoretical bench for a plate not turned in the new reference mark user (displacement for a not turned plate being vertical, new displacement is a function of the projection of the axis Z). In the local reference mark, the projection of axis Z is as follows:***

*sin cos**sin sin, with = 20. and =*.  
30

*cos*

## ***20 Summary of the results***

***The results obtained show that:***

***Identical · A grid (standard of surface meshes and orientation of the meshes), change of reference mark user does not influence the constraints;***  
***· Because of orthotropism of the problem, there exists a considerable sensitivity to the orientation triangular surface meshes (the precision of calculations passes from 1 to 11% for constraints and from 0.17 to 0.95% for displacements). This sensitivity does not disappear in refining the grid. This point is thus to take into account at the time of the comparison of***

## ***1*** ***Problem of reference***

### ***1.1 Geometry***

0.2

*A4*  
*Plate*

*A3*  
*offset*

*L14*  
*Plan purifies*

*L12*

*Z*

*y*  
*A1*  
*A2*

*Plate reference*

*not offset*

X

*One represented here the plate offset compared to the plan of diagram (which is confused here with the plan*

*inferior of the offset plate).*

*To avoid overloading the diagram, one does not trace the plate of not offset reference, for which the plan of diagram is also the average plan.*

## **1.2**

### ***Properties of materials***

*The material constituting plate is characterized by the following data:*

*EL=20000.Pa ET=20000.Pa EN=20000.Pa*

*LN = 0. LT = 0 TN = 0. GLT=2000.Pa GLN=0. GTN=0.*

*RHO= 1000.kg/m<sup>3</sup>*

## **1.3**

### ***Boundary conditions and loadings***

*The L14 mesh is embedded DX=DY=DZ=0.*

*DRX=DRY=DRZ=0.*

*One applies the forces to the L12 mesh*

*FX=1000.N MY=100.N.m*

*on the offset plate*

*FX=1000.N*

*on the not offset plate*

*These loadings are applied by means of FORCE\_ARETE of AFFE\_CHAR\_MECA in the plan of diagram.*

### **Note:**

*The fact of applying a force FX to the plate offset to the level of the plan of diagram generates one moment MY which should be compensated for to find itself under conditions purely membrane on the level of the offset plate.*

## **Reference solution**

**2.1**

### **Method of calculation used for the reference solution**

*The calculation of the membrane type with the not offset plate is used as reference. Nonregression by report/ratio with the results obtained by this first calculation is checked.*

**2.2**

### **Results of reference**

*They are consisted of the values of the field of displacement  $DX$ ,  $DY$ ,  $DZ$ ,  $DRX$ ,  $DRY$  with nodes 66 and 52*

*(for the  $DKT$  and  $DST$ ) and with the nodes  $N1$  and  $N16$  (for the  $DKQ$  and the  $DSQ$ ) and of the calculation of the frequencies of the first 4 modes.*

**2.3**

### **Uncertainty on the solution**

*Uncertainty is null since it is about the same calculation carried out by two different ways.*

***SSLS117 - Offsetting of plates  
nonsymmetrical***

***Summary:***

***This test validates the offsetting of nonsymmetrical simple plates compared to the plan of the grid or plan of diagram (key word OFFSETTING of order AFFE\_CARA\_ELEM).***

***The reference is given by a first resolution where one models double-layered made up of two layers various thicknesses and of two materials.***

***It is used to validate the second calculation where one models two layers offset compared to the plan of the grid.***

***It differs from test SSLS111 only by the fact that the 2 layers are different thicknesses.***

***Four modelings implement elements DKT, DKQ, DST, DSQ.***

## ***Properties of materials***

***The material constituting the first layer is orthotropic and is characterized by the data following:***

***EL=20000. 106 Pa***

***ET=20000. 106 Pa***

***LT = 0.3***

***GLT=2000. 106 Pa***

***The material constituting the second layer is also orthotropic and has the following characteristics:***

***EL=15000. 106 Pa***

***ET=15000. 106 Pa***

***LT = 0.3***

***GLT=1500. 106 Pa***

## ***1.3***

### ***Boundary conditions and loadings***

***The A1 node is embedded***

***DX=DY=DZ=0.***

***DRX=DRY=DRZ=0.***

***The A2 node is blocked according to following ddls: DX=DY=0.***

***One applies nodal forces FZ=1000 NR to the A3 node, and one applies the loading distributed (key word FORCE\_COQUE) on the meshes m1, m2 and m3:***

***FX=200 NR***

***FX=500. N/m2 FZ=500.***

***N/m2***

***MX=100. N/m***

***MY=40. N/m***

***The selected loading utilizes requests out of membrane and inflection.***

***11 Summary of the results***

***With regard to displacements for the modelings DKT and DKQ, the results obtained with 2 offset hulls differ from to the more 2% compared to the reference solution. For the others modelings, one obtains to the maximum of the errors of 4% for DST and 6% for the DSQ. For these two last modelings, the error is more important because the calculation of transverse shearing is not not are equivalent between the double-layered one and the two offset plates.***

***Indeed, transverse shearing is supposed to be constant in the thickness of each DST element or DSQ; this transverse shearing is an average shearing. An average value is thus obtained for each plate offset, overall different from average transverse shearing on the double-layered plate.***

***This is marked even more for the efforts, where the differences remain lower than 5% for modelings DKT (A and B) but reach 11% for modeling C and 89% for modeling D. Being given the nature of the test, one cannot know a priori if the problem comes from the hulls and plates multi-layer or of offsetting. An anomaly is in the course of treatment on this problem.***

**SSLS118 - Square plate posed subjected  
with a sinusoidal pressure**

**Summary:**

**One treats the case of a multi-layer full-course square plate then, simply supported and subjected to one**

*sinusoidal pressure.*

*One calculates displacement in the center, the constraints, with the lower interfaces*

*xx*

*yy*

*xy*

*xz*

*yz*

*averages and higher, efforts of membrane NR, NR, NR, efforts sharp T, T and them*

*xx*

*yy*

*xy*

*X*

*y*

*moments M, M and Mr.*

*xx*

*yy*

*xy*

*The test gathers 14 modelings: with regard to modelings A with F, the results obtained are compared for modelings DKQ, DSQ, DKT, DST, COQUE\_3D with triangular meshes and COQUE\_3D with rectangular meshes.*

*Modelings G and H make it possible to test the results in a reference mark user different from the total reference mark.*

*Modelings I and J measure the sensitivity of the results to the smoothness of the grid, for the configuration*

*DSQ.*

*Modelings K with NR relate to the multi-layer plate, for modelings DST and DSQ, in reference mark total and user. They make it possible to estimate the distribution of the plane constraints and transverse shearing inside the plate.*

**Date:**

**16/11/01**

**Author (S):**

**P. MASSIN, NR. RAHNI Key**

**:**

**V3.03.118-A Page:**

**3/62**

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**The analytical solution of reference is based on the theory of Coils-Kirchhoff, usually used for the plates known as "thin" [bib1].**

**Taking into account the problem and in any point of the plate, one has for the calculation of the arrow:**

**F a4**

**0**

**X**

**y**

**W =**

**sin sin**

**4 4 D**

**has**

**has**

**with:**

**3**

**=**

**Eh**

**D**

**, F = 1, has = 1 and = 0.25**

**12(**

**2**

**1 -) 0**

**For the calculation of the moments, the theory leads to the following expressions:**

**M = 1+ sin sin**

**xx**

**(**

)  
*X*  
*y*  
*has*  
*has*  
*M*  
*= M*

*yy*  
*xx*  
*M*  
*= - 1 - cos cos*

*xy*  
(  
)  
*X*

*y*  
*has*  
*has*  
*2*  
*F*  
*with*  
*0*

*has*  
*=*  
*2*  
*4*

*For the sharp efforts, one obtains:*

*F has*  
*0*  
*X*  
*y*  
*T =*  
*cos sin*  
*X*

*2*  
*has*  
*has*  
*F has*  
*X*

*y*  
*T*  
*0*  
*=*  
*sin cos*  
*y*

*2*  
*has*  
*has*

*For a homogeneous plate, the plane constraints are given by:*

*M*  
*xx*  
*xx*  
*Z A M*

*yy*  
*= [ ]*

*yy*

*M*  
*xy*  
*xy*  
*12*  
*with [ ]*  
*With =*  
*and Z the position in the thickness of the plate*  
*3 [I]*  
*H*

*and stresses shear transverse by:*

*T*

$xz = [D$   
,  
 $1 (Z)] X$

$T$   
 $yz$   
 $y$   
 $6 H2$

with  $[D$

$1 (Z)]$

=  
-  $z^2$   
3  
 $[I]$   
 $H$

2

## 2.2

### *Results of reference*

*For each modeling, one calculates:*

- in the center of the plate, displacement,*
- in the center of the plate and in the middle of side AB, the constraints, on*

*xx*

*yy*

*xy*

*xz*

*yz*

*plans:*

*-*

*inferior, means and superior of the plate in the full-course case,*

*-*

*inferior, means and superior of each section in the multi-layer case (5 layers),*

- in the center, the corners and in the middle of sides AB and AD, the efforts of membrane NR, NR,*

*NR,*

*xx*

*yy*

*xy*

*sharp efforts T, T and the moments M, M and Mr.*

*X*

*y*

*xx*

*yy*

*xy*

*The expression of these quantities to the points O, A, B, C, D gives:*

*W M*

*M*

*M*

*T*

*T*

*xx*

*yy*

*xy*

*X*

*y*

*O*

*(2*

*3 1- )*

#### ***15.4 Remarks***

***The value of reference of displacement to the point O is obtained by projecting calculated displacement***

***for modeling D in the reference mark turned (displacement for modeling D being vertical, it new displacement is a function of the projection of axis Z).***

***In the local reference mark, the projection of axis Z is as follows:***

***sin cos***

*sin sin, with = 20. and =*

.  
30

*cos*

*In addition, the expression of the sinusoidal pressure in the turned reference mark becomes:*

*Error! Objects cannot be created starting from the field codes of working.*

#### ***17.4 Remarks***

***The value of reference of displacement to the point O is obtained by projecting calculated displacement for modeling E in the reference mark turned (displacement for modeling E being vertical, it new displacement is a function of the projection of axis Z). In the local reference mark, the projection of axis Z is as follows:***

***sin cos***

***sin sin, with = 20. and =***

***.  
30***

***cos***

***In addition, the expression of the sinusoidal pressure in the turned reference mark becomes:***

***cos cos X + sin cos y - sin Z***

***cos y - sin X***

***P = F sin***

***0***

***sin***

***62/62***

### ***31 Summary of the results***

***The results obtained show that:***

- modeling DSQ provides a more precise estimate of the constraints and efforts edges (<5%) than modeling DKQ (=20%). The estimate of the moments is equivalent for two modelings,***
- the estimate of the constraints is more precise with modeling DKT (<2%) compared to modeling DST (<3,5%). The shearing action is on the other hand better estimated by DST (<10% for DST and <20% for DKT),***
- for the configurations COQUE\_3D triangle or quadrangle, the estimate of the constraint of transverse shearing is constant in the thickness of the plate, in accordance with assumptions of modeling,***
- 
- results expressed in the reference mark user for the DST configurations and COQUE\_3D are identical to those expressed in the total reference mark,***
- 
- the refinement of the grid for configuration DSQ improves the estimate of constraints, of the sharp efforts and the moments; the tendency is reversed in what relate to displacement,***
- 
- the multi-layer configuration makes it possible to visualize the distribution of the plane constraints and***
- of transverse shearing in the thickness of the plate, and to confirm the theory, with to know a linear for the plane constraints and parabolic distribution for shear stresses; in addition, the rotation of the reference mark does not influence the values constraints,***
- 
- in a general way, with the nodes where one awaits constraints or efforts analytically null, the numerical results obtained are not correct owing to the fact that the estimates are made mesh by mesh then extrapolated with the nodes. Even their values realised with the nodes in question are not inevitably null.***

**with a sharp effort at its end**

## **Summary:**

***This test represents a static calculation of an embedded hook subjected to a shearing force, consisted of one elastic material. This test makes it possible to validate following modelings finite elements:***

- ***DST (QUAD4),***
- ***DKT (QUAD4),***
- ***COQUE\_3D (QUAD9),***
- ***COQUE\_3D (TRIA7),***
- ***linear 3D (HEXA8) and quadratic (HEXA20).***

***One studies blocking in transverse shearing particularly there.***

### ***Reference solution***

***This test makes it possible to test blocking in transverse shearing as well as the effects of the rigidity of rotation around the normal. It makes it possible to validate the choice  $COEF\_RIGI\_DRZ = 1. E05$ , value by defect of this coefficient. This multiplicative factor makes it possible to affect a fictitious rigidity around normal of the elements of plate by multiplying minimal rigidity according to the other directions by it coefficient in order to avoid the singular matrices of rigidity.***

*Problem of reference*

*1.1 Geometry*

*Cylindrical reserve of average radius  $R = 5.7$  m, thickness  $E = 0.04$  m and height  $L = 16$  m, simply supported at its base (rotation is free), and subjected to an internal hydrostatic pressure.*

***Average radius:  $R$***

***= 5.7 m***

***Thickness:***

***$E = 0.04 \text{ m}$***

***Height:***

***$L = 16 \text{ m}$***

***1.2***

***Material properties***

***The properties of materials constituting the plate are:***

***Material 1: isotropic rubber band:***

***Young modulus***

***$E = 2.1 \cdot 10^{11} \text{ Pa}$***

***Poisson's ratio***

***= 0.3***

***Material 2: orthotropic rubber band:***

***$E_L = 1 \cdot 10^{10} \text{ Pa}$***

***$E_T = 2.1 \cdot 10^{11} \text{ Pa}$***

***$G_{LT} = 0.45 \cdot 10^{10} \text{ Pa}$***

***$G_{TN} = 0.35 \cdot 10^{10} \text{ Pa}$***

***$\nu_{LT} = 0.075$***

***The axis  $L$  is confused with axis  $Z$ .***

***1.3***

***Boundary conditions and loadings***

***Base  $Z = 0$  simply supported***

*internal pressure varying linearly according to Z:  $p(Z) = P_0 \cdot (L-z) / L$   
with  $P_0 = 15000 \text{ Pa}$ .*

***6.5 Remarks***

***To obtain a correct result, it is necessary to take guard with the convention adopted for NU\_LT for hulls multi layers (DEFI\_COQU\_MULT), which is different from that used for ELAS\_ORTH:***

***Here, it is necessary to take Nu\_LT such as NuTL=ET/EL\*NuLT, that is to say NU\_LT = 0.014285714).***

## 7

### ***Summary of the results***

***The results of four modelings are very close to the analytical solution: to the maximum 0.4% variation for modelings COQUE\_3D and DKT, and less than 2% of variation for modeling axisymmetric, which is explained by the fact why the analytical solution is a mean solution hull.***

***This test thus validates on the one hand the efforts of pressure varying linearly with the geometry, for thin hulls, and in addition the taking into account of orthotropic elasticity.***

***SSLS121 - Plate laminated subjected***  
***with elementary loadings***

***Summary:***

***This test represents the quasi-static calculation of a laminated plate, composed of 3 layers of material orthotropic, subjected to 4 elementary loadings.***

***The plate is modelled in finite elements DST (meshes QUAD4), it is located in a plan XZ and is inclined 48,5 degrees compared to X (to check the changes of reference mark).***

***In this test, the plane constraints and stresses shear transverse, are compared with one analytical reference solution.***

***Summary of the results***

***Results in conformity with the reference solution.***

***One could expect to find exactly same displacement to the three point A, B and C. difference at the point C comes from not-symmetry from the grid. The grid is slightly more distorted around this point, which explains the fall of precision, which remains nevertheless very good, as well for element HEXA8 for the SHB8.***

**SSLS124 - Beam in inflection with various  
twinges**

**Summary:**

**This test represents a calculation quasi-static of a beam in inflection, embedded at an end, and subjected to a vertical force at the other end. This test makes it possible to validate for a linear elastic design, and four values of twinge (variable thicknesses) in each of two modelings:**

- Finite elements SHB8 for a regular grid (modeling A)**
- Finite elements SHB8 for a nonregular grid (modeling B)**

**Displacements obtained are compared with the elastic analytical solution of a beam in inflection. This test allows to assemble the limits of the elements in term of twinge, on the one hand, and to show their good**

*convergence for a very irregular grid, in addition.*

***Summary of the results***

***In the case of the regular grid, from good solutions are obtained. The quality of the solution declines nevertheless when the twinge of the element (side ratio/thickness) reached 200.***

***In the case of the not-regular grid, whatever the twinge of the element, one tends to underestimate the rigidity of the beam from approximately 4%.***

***This test can be supplemented by a modeling 3D and to be applied to the elements of COQUE\_3D MEC3QU9H like with elements DKT.***

external pressure***

***Summary:***

***This test represents a calculation of stability of a free thin cylindrical envelope at its ends subjected to an external pressure. One calculates the critical loads leading to the elastic buckling of Euler. The matrix of geometrical rigidity used in the resolution of the problem to the eigenvalues is that which is due to initial constraints.***

***He makes it possible to validate modeling finite elements SHB8.***

***The critical load and the clean mode obtained are compared with an analytical reference solution.***

***DEMO006 Optimization of the radius of curvature  
of a bent piping***

***Summary:***

***This test of demonstration illustrates the use of the language python in Code\_Aster.***

***The objective of this case-test is to optimize the value of the radius of curvature of a piping via a loop python.***

*The radius of curvature is modified repeatedly. The optimal value is obtained when the maximum constraint of Von Mises is lower than a threshold.*

*The language python, in this case-test allows repeatedly:*

- 
- to modify the file describing the geometry of the elbow,*
- 
- of launching GMSH in order to net the elbow,*
- 
- to recover the maximum constraint of Von Mises,*
- 
- to evaluate a criterion of stop of the iterations,*
- 
- of launching GMSH to carry out an interactive postprocessing.*

*This case-test takes again the problem of the case-test forma01f: bent piping, made up of an elastic material linear, subjected to a force applied at its end, modelled by elements of hulls DKT.*

*Note:*

*To have the interactive functions of visualization, to put interactive = 1 at the beginning of the file of order.*

## **1 Problem of reference**

### **1.1 Geometry**

**The study relates to a piping including/understanding two right pipes and an elbow [Figure 1.1-a].**

**The geometrical data of the problem are as follows:**

- .  
**length LG of the two right pipes is 3 m,**
- .  
**initial the Rc ray of the elbow is 0.3 m,**
- .  
**the angle of the elbow is 90 degrees,**
- .  
**the thickness of the right pipes and the elbow is 0.02 m,**
- .  
**and the ray external Re of the right pipes and the elbow is of 0.2 Mr.**

## **1.3**

### **Boundary conditions and loadings**

- **Boundary conditions: embedding on the level of section A,**
- **Chargement: force constant FY directed according to the axis Y and applied to the section B.**

**The value of FY is calculated to leave:**

**average radius:  $RMOY = 0.19$ ,**

**total force applied:**

**2**

**$FTOT = 500000 \text{ NR/m}$ ,**

**Its expression is as follows:**

**$FY = FTOT (2 RMOY) (418828.8)$**

- **The limiting constraint of Von Mises is of  $2.0E+09 \text{ N/m}^2$**

## **2**

### **Reference solution**

#### **2.1**

##### **Method of calculation used for the reference solution**

**The reference solution is obtained numerically. It is thus only about one test of not regression.**

#### **2.2**

##### **Results of modeling**

**The optimal value of the radius of curvature, respecting the criterion put  $< 2.109 \text{ N.m}^{-2}$  is of 1.1m, obtained after 5 iterations. With each iteration the radius of curvature is increased by 0.2m.**

**3 Modeling**  
**With**

**3.1**  
**Characteristics of modeling**

## **Modeling in elements hulls (DKT).**

**Appear 3.1-a: geometry and grid of the half roll (initial RC)**

### **3.2**

#### **Characteristics of the grid**

**The grid is regenerated with each iteration because of the modification of the radius of curvature of geometry. However the topological characteristics of the grid are unchanged:**

- 
- 1013 meshes (900 TRIA3, 110 SEG2, 3POI3)**
- 
- 507 nodes.**

**The groups of meshes correspond to:**

- 
- GM30 <=> surface of the PIPE**
- 
- GM28 <=> section B (effort)**
- 
- GM31 <=> not A1 (- R, 0, 0)**
- 
- GM27 <=> section A (embedding)**
- 
- GM29 <=> SYMMETRY**

### **3.3 Orders**

#### **Aster**

**This paragraph describes the algorithm used in the command file and presents the orders *Code\_Aster* used.**

.

**Initialization of certain variables:**

**Radius of curvature:  $Rc = 0.3$**

**Criterion of convergence:  $crit = 2.0E+09$  (forced of Von Mises targets)**

.

**One enters the loop python whose criterion of stop relates to the constraint max of Von Settings. As long as the criterion is not respected, the following instructions are carried out:**

**Rebuilding of the grid:**

**one**

**redefines**

**$Rc$  in the geometrical file *.geo* of GMSH**

**one launches gmsH via python to generate the file of grid *.msh***

**Reading of grid (PRE\_GMSH) and generation of grid (LIRE\_MAILLAGE). One uses DEF1\_GROUP to re-elect the groups of meshes according to the correspondence:**

**# GM30 <=> PIPE**

**# GM28 <=> EFOND**

**# GM31 <=> A1**

**# GM27 <=> ENCAST**

**#**

**GM29**

**<=>**

**SYMMETRY**

**Definition of the finite elements used (AFFE\_MODELE). The right pipes and the elbow are modelled by elements of hull (DKT).**

**Reorientations of the normals to the elements: one uses MODI\_MAILLAGE to direct all elements in the same way, with a normal turned towards the interior.**

**Definition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU). mechanical characteristics are identical on all the structure.**

**Assignment of the characteristics of the elements hulls (AFFE\_CARA\_ELEM): thickness, vector V defining the reference mark of examination (key word ANGL\_REP)**

**Definition of the boundary conditions and loading (AFFE\_CHAR\_MECA).**

**Piping is embedded in its base, on all the nodes located in the Y=0 plan.**

**Piping presents a symmetry plane Z=0.**

**One calculates an effort distributed FY directed according to the axis Y and applied to the section B, (the effort distributed is such as the resultant  $2\pi \cdot R \cdot M \cdot OY$ .  $FY = FTOT$ ,  $FTOT$  being the total force that one wishes to apply). To apply the effort to the section B, one will use FORCE\_ARETE.**

**Resolution of the linear elastic problem (MECA\_STATIQUE).**

**Calculation of the stress field by elements to the nodes for each loading case (option "SIGM\_ELNO\_DEPL"). The constraints are calculated in the definite local reference mark for each element using the vector V (preceding key word ANG\_REP). To use NIVE\_COUCHE to define the level of calculation in the thickness.**

**Calculation of the stress field equivalent by elements to the nodes calculated from stress field (option "EQUI\_ELNO\_SIGM").**

**Calculation of the preceding fields to the nodes (options "SIGM\_NOEU\_DEPL", Buckle python of optimization of the radius of curvature "EQUI\_NOEU\_SIGM")**

**Impression of results (IMPR\_RESU).**

**Determination of a table containing calculations of averages of the stress field equivalent to the nodes. ("POST\_RELEVE\_T")**

**Extraction of component VMIS of the preceding table via python.**

**Test of stop:**

**If VMIS is higher than CRIT, then one reiterates with  $Rc=Rc+0.2$**

**If not one leaves the loop python.**

### **Summary of the results**

*As a whole, the results obtained are very satisfactory:*

.

*the maximum change is 1.1% on displacements,*

.

*the maximum change is 0.21% at the bending time.*

*The value of the normal effort is far away from the reference solution. The result would be more precise if one*

*used a finer grid [bib1].*

***V3.03 booklet: Linear statics of the hulls and the plates***

***Document: V3.03.502***

***SSLS502 - Orthotropic cylinder subjected to a line of load***

***Summary:***

***This test represents quasi-static calculation, of a short orthotropic cylinder and an orthotropic long cylinder***

***subjected to a line of load. Their ends, the cylinders rest on rigid diaphragms. This case test makes it possible to validate modeling finite elements DST with meshes TRIA3 and QUAD4, a material***

***homogeneous orthotropic.***

***Displacements and the efforts obtained are compared with a reference solution experimental like to an analytical solution.***

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**We will use for this test two reference solutions, one experimental, resulting from work from Schwaighofer and Microys [bib2], the other drawn from work of Batoz in theory of the deep hulls [bib1].**

**2.2**

**Results of reference**

**The results of reference are as follows:**

**Roll (A and B) short**

**Batoz [bib1]**

**Experiment [bib2]**

**Displacement W at the point F**

**0.35 104 m 0.6**

**104 m**

**Displacement W at the point C**

**0.7 103 m**

**0.6 103 m**

**Displacement W at the point D**

**0.25 104 m**

**0.1 103 m**

**Constraint xx at the point F**

**0.35 MPa**

**0.325 MPa**

**Constraint yy at the point F**

**0.50 MPa**

**0.60 MPa**

**Roll long (C and D)**

**Batoz [bib1]**

**Experiment [bib2]**

**Displacement W at the point F**

**1.32 10<sup>3</sup> m**

**1.35 10<sup>3</sup> m**

**Displacement W at the point C**

**2.45 10<sup>3</sup> m**

**2.46 10<sup>3</sup> m**

**Displacement W at the point D**

**0.35 10<sup>3</sup> m**

**0.51 10<sup>3</sup> m**

**Constraint xx at the point F**

**1.68 MPa**

**1.9 MPa**

**Constraint yy at the point F**

**1.8 MPa**

**1.55 MPa**

**2.3**

**Uncertainties on the solution**

**~ 5% with regard to the solution of Batoz, undoubtedly much more - ~30% - for the solution experimental.**

## **8.2 Remarks**

- The value of coefficients  $CISA_L$  and  $CISA_T$  are not available. As the structure is thin ( $h/R=0.045$ ), that the effects of transverse shearing are negligible, us are supposed thus imposed  $CISA_L=CISA_T=1010$ .
- Displacement  $W$  normal is expressed in the local cylindrical reference mark ( $R, Z$ ), it acts of normal displacement with the element of hull.

## **11 Summary of the results**

*The results are as a whole satisfactory. The specific variations which appear at the points tested, in particular the point D, seem due to the experimental uncertainty, undoubtedly reinforced by an uncertainty as for the graphic taking away.*

*A contrario, the solutions suggested by Batoz in theory “deep hulls” are well checked by four modelings, with relative errors of less than 5% for the long cylinder.*

*It appears that:*

- modelings TRIA3 and QUAD4 are appreciably equivalent for this problem,*
- the relative errors are much weaker for the long cylinder (modelings C and D) that for the cylinder runs (modelings A and B): at the point F, the error is reduced of a factor 10 compared to the reference solution of Batoz,*
- the refinement of the grid does not minimize in a decisive way the relative variations, so much with TRIA3 that with the QUAD4.*

*It is thus noted that the results are degraded when the report/ratio length on the diameter decrease, indeed the geometrical effects become important with this type of modeling. It would be desirable to be able to carry out a calculation in finite elements of hulls in orthotropic medium, in order to*

*to better take into account the curve, the plates constituting a borderline case.*

**SSLS503 - Plate laminated in inflection stacking  
antisymmetric simply supported**

**Summary:**

*This test represents a quasi-static calculation of a laminated plate, in antisymmetric inflection stacking, simply supported, subjected to a pressure uniformly distributed.*

*4 modelings make it possible to validate:*

- modelings finite elements DKT (QUAD4, TRIA3) and DST (QUAD4, TRIA3) in the case of one composite material (3 different layers of orientation),*
- stresses shear transverse.*

*Displacements and the constraints obtained are compared with an analytical reference solution.*

*2 sleep (z=0),*

### **2.3**

#### ***Uncertainties on the solution***

- The reference solution is given for a number of terms in the series equal to 25.*
- The factor of correction of transverse shearing used is 5/6.*
- With an important twinge (a/h=100), the transverse level of shearing is weak and thus difficult to obtain with precision. There is then an uncertainty on the values of constraint ij calculated during the validation of test VPCS, the differences obtained by software on the components of shearing is about 10%.*

## 4.2 Remarks

*The constraints are expressed in the reference mark of orthotropism defined by ANGL\_REP (AFFE\_CARA\_ELEM), and by the normal of the element.*

*Components SIXX, SIYY and SIYZ are the average values of the two convergent meshes with points A and C.*

*The variation obtained on SIXZ is due to the difference in modeling of transverse shearing: in reference, one uses a coefficient of transverse correction of shearing of 5/6. In Code\_Aster, one calculates the distribution of shearings in the thickness, presumedly parabolic in each sleep.*

*The sign of SIXZ is opposed to that of the reference solution.*

## 8.2 Remarks

Components *SIXX*, *SIYY* and *SIYZ* are the average values of the two convergent meshes with points *A* and *C*.

The variation obtained on *SIXZ* is due to the difference in modeling of transverse shearing: in reference, one uses a coefficient of transverse correction of shearing of 5/6. In *Code\_Aster*, one calculates the distribution of shearings in the thickness, presumedly parabolic in each sleep.

The sign of *SIXZ* is opposed to that of the reference solution.

The other variations are probably due to the anisotropy of the triangular grid.

## **11 Summary of the results**

*· Déplacements: some is modeling used (DKT or DST) the results are satisfactory, the maximum error is lower than 0.7%.*

*· Plane Contraintes: the results are more precise with modeling DKT, the error is lower than 1% except for SIXY (QUAD4) where the error is 5%. For DST modeling the error is higher (<8%) with an important variation on SIXX (28%) for mesh TRIA3.*

*· Transverse Cisaillement: some is modeling used (DKT or DST) the results obtained with the quadrangular grids are closer to the reference solution than those obtained with triangular grids. In the first case the error on the component SIXZ is lower than 15%, and the error on SIYZ is lower than 3%, while in the second case, the error on SIXZ is 35% and that on SIYZ lies between 2% and 24%. Except worse precision of the triangular grids because of their anisotropy, the variation which remains with quadrangular grids is due to the difference in modeling of shearing transverse: in the reference, one uses a coefficient of transverse correction of shearing of 5/6. In Code\_Aster, one calculates the distribution of shearings in the thickness, supposed parabolic in each layer.*

***SSLV04 - Hollow roll in plane constraints***

***Summary:***

***This test is drawn from Guide VPCS (test SSLV04/89) and has as an aim a hollow roll charged in pressure intern.***

*This three-dimensional problem is dealt with with various modelings:*

- *in 3D: 9 modelings (pentahedral, hexahedrons, tetrahedrons and pyramids, degrees 1 and 2),*
- *in 2D forced plane: 4 modelings (triangles and quadrangles degrees 1 and 2, quadrangles with 9 nodes),*
- *in axisymmetric 2D: 3 modelings (triangles and quadrangles degrees 1 and 2, quadrangles with 9 nodes).*

*The functionalities tested are:*

- *pressure distributed,*
- *basic effect (with fixed or variable pressure),*
- *imposed displacements,*
- *matrices of rigidity,*
- *deformations and constraints with the nodes,*
- *nodal reactions (modeling K).*

*There are 16 modelings.*

## **2**

### ***Reference solution***

## **2.1**

### ***Method of calculation used for the reference solution***

*In constraint planes (cylinder on free board at the ends)*

$$zz = 0$$

*2*  
*B*

*has*  
*rr*  
*= P*  
*1-*

$$b^2 - a^2$$

*R 2*  
*2*  
*B*

*has*  
*= P*  
*1+*

$$b^2 - a^2$$

*R 2*  
*R = 0*  
*P*  
*a^2*

$$ur = (I) + (I+) R$$

*One obtains:*

$$for$$
$$= 0.1$$
$$= 59.106$$

-

$\rho$   
 $= 0.2$   
 $= 40. 10^6$   
 $R$   
 $U$   
 $R$   
 $U$   
 $-$   
 $R$   
 $R$   
 $= 60.$   
 $-$   
 $= 0.$   
 $rr$   
 $rr$   
  
 $= 100.$   
 $= 40.$   
 $= = 0.$   
 $= = 0.$   
 $zz$   
 $R$   
 $zz$   
 $R$

*Passage in the system of Cartesian axes:*

$$\begin{aligned}
 &2 \\
 &2 \\
 &xx \\
 &= rr \cos^2 + \sin^2 - 2 R \sin \cos
 \end{aligned}$$

$$\begin{aligned}
 &2 \\
 &2 \\
 &yy \\
 &= rr \sin^2 + \cos^2 + 2 R \sin \cos
 \end{aligned}$$

$$\begin{aligned}
 &2 \\
 &2 \\
 &xy \\
 &= rr \sin \cos - \sin \cos - 2 R (\cos - \sin)
 \end{aligned}$$

***with:***

- = 0° at points A and B,***

**:**

**V3.04.004-E Page:**

**35/36**

### **33.4 Remarks**

**Contrary to modeling NR, one tests here a basic pressure and effect variables in function time. A linear variation of the pressure involves a linear variation of the constraints.**

### **34 Results of modeling P**

· *The results are more precise with elements of order 2.*

· *The problem is adapted more to an axisymmetric modeling. The results are better.*

· *The grids remain insufficient for the elements 3D of order 1: constraints and deformations modelings A, C, E and L (especially for modeling L in PYRAM5).*

· *The pyramids give results similar to the other elements 3D, with equivalent grid.*

· *Modelings NR and P with basic effect and pressure constant or variables give of good results.*

**SSLV07 - Stretching of a parallelepiped**

**under its own weight**

**Summary:**

**This static test 3D makes it possible to validate the following functionalities:**

- loading in actual weight (gravity or internal force) and in uniform pressure,**
- calculation of the potential energy of the structure,**
- estimator of error in residue (modeling B).**

**It includes/understands 3 modelings. Its interest lies in the description of the effect of the Poisson's ratio (of contraction).**

## **Handbook of Validation**

### **V3.04 booklet: Linear statics of the voluminal structures**

**Document: V3.04.100**

#### **SSLV100 - Hollow roll in plane deformations**

##### **Summary:**

This test makes it possible to validate the elements of plane deformation on the following functionalities:

- pressure distributed,
- matrix of rigidity,
- imposed displacements:

- by

ddl,

-

by face of element.

It includes/understands 4 modelings.

The 3 first correspond to elements of the different type (linear and quadratic).

The last validates the displacements imposed by face (blocking of the normal component).

**SSLV104 - Beam in rotation**

**Summary:**

This test makes it possible to validate the linear elastic design of a slim beam subjected to a rotation of one of its ends. Three modelings are tested: elements 3D (HEXA20) and elements of COQUE\_3D (QUAD9 and TRIA7). That tests the inertias of rotation, without taking account of the elementary terms of stiffening centrifuge (cf [V3.04.105]).

The reference solution is analytical (1D). The results coincide perfectly with the reference solution.

## **9 Summary of the results**

The coincidence of the results with the analytical solution makes it possible to validate the loading due to the forces of inertia of rotation.

Modeling COQUE\_3D with MEC3QU9H gives the solution with very few elements.

One will refer to test SSLV105 [V3.04.105] to evaluate the effect of the stiffening centrifuges for the element 3D, HEXA20.

**V3.04 booklet: Linear statics of the voluminal structures**

**Document: V3.04.105**

**SSLV105 - Stiffening centrifuges of a beam**

**in rotation**

**Summary:**

Test of Mechanics of the structures in linear static analysis.

The geometry is that of a slim beam subjected to a rotation around one of its ends. Only one modeling: elements 3D (HEXA20). One tests here the inertias of rotation (like test SSLV104) with taking into account of the centrifugal stiffening.

The reference solution (analytical) takes into account the term of additional rigidity due to rotation. results are identical to the reference solution.

**1**

**Problem of reference**

**1.1 Geometry**

The structure is made up of a directed slim beam carried in space by the axis of vector director (1, 1, 1).

0.5 m

Z

Y

0.02 m

X

Embedded face

Square section of surface: 4.0 104 m<sup>2</sup>

Length of the beam: 0.5 m

**1.2**

### **Material properties**

E = 2. 1011 Pa

= 0

= 7800 kg/m<sup>3</sup>

**1.3**

### **Boundary conditions and loadings**

Free beam fixed in rotation around an axis perpendicular to its greater dimension and passing by the center of the embedded face.

Co-ordinates of the vector rotation: (1, 0, 1).

Number of revolutions: = 3000 rd/s.

The important value number of revolutions does not have anything physics.

## **Reference solution**

**2.1**

### **Method of calculation used for the reference solution**

In local reference mark of the beam: the equation relating to  $U_x$  displacement (without neglecting

lengthening) is:

$$2U_x + 2X + U = 0$$

2  
(  
X)  
X  
E  
With the boundary conditions  $U(0) =$

$$U_x(L) = U(L) = 0$$

X  
xx

2

One poses: =

E

By integrating the preceding differential equation one obtains, in the reference mark of the beam:

$$U(X) = \cos(X) - X$$

$$U = U =$$

X

y

2

0

L)

The displacement of any points of the beam is thus written in the total reference mark:

$$1 \sin R$$

U

=

-

$$X(X, Y, Z)$$

( )

$$3 \cos$$

(

R

*L*)  
1 sin *R*

*U*  
=

-  
*y* (*X*, *Y*, *Z*)  
( )  
3 cos

(  
*R*  
*L*)  
1 sin *R*

*U*  
=

-  
*Z* (*X*, *Y*, *Z*)  
( )  
3 cos

(  
*R*  
*L*)  
with *R*

=  
 $X^2 + Y^2 + Z^2$

## 2.2

### Results of reference

Values of three displacements in the center of the section furthest away from the axis of rotation.

## 2.3

### Uncertainty on the solution

Without object (analytical solution).

***SSLV109 - Full cylinder in nonuniform pressure***  
***mode 1***

***Summary:***

*This test validates all the elements of Fourier (triangles and quadrangles of degrees 1 and 2) in elasticity.*

*functionalities are as follows:*

- variable pressure in space,*
- imposed displacements,*
- matrices of rigidity Fourier mode 1,*
- forced with the nodes Fourier mode 1,*
- recombination of Fourier on displacements and constraints (modeling A),*
- transverse isotropic material (modeling F).*

*The test has a quadratic analytical solution in displacements.*

*The interest of the test lies in:*

- the comparison between solution calculated and analytical solution on the various finite elements,*
- the comparison between the results and Code PERMAS on elements TRIA6 (modeling A).*

*Handbook of Validation*

*V3.04 booklet: Linear statics of the voluminal structures*

## 4.2 Remarks

*The analytical solution is found with a precision  $< 0.02\%$  for displacements and  $< 0.1\%$  for the constraints.*

*With a numerical formula of integration at 6 points of GAUSS (instead of 3) to calculate the stiffness, one would find the relation at 1010 close (like PERMAS).*

***SSLV110 - Elliptic crack in an infinite medium***

***Summary:***

***It is about a test in statics for a three-dimensional problem. This test makes it possible to calculate the rate of refund of energy total and local on the bottom of crack by the method.***

*The rays of the crowns of integration are variable along the crack, and the rate of refund of energy room is calculated according to 2 different methods (LEGENDRE and LAGRANGE).*

*The interest of the test is the validation of the method in 3D and the following points:*

- comparison between the results and an analytical solution,*
- stability of the results according to the crowns of integration,*
- comparison between 2 methods different for calculation from G local,*
- 2 cases of equivalent loadings (pressure distributed and voluminal loading).*

*This test contains 4 different modelings.*

*The 3rd modeling tests the derivative of G compared to the parameters material and loading.*

**Document: V3.04.111**

**SSLV111 - Estimator of error on a plate**

**perforated in linear elasticity**

**Summary:**

***This test validates and compares the 2 versions of the estimator of error of Zhu-Zienkiewicz (version 1 of 1987, noted***

***ZZ1, and version 2 of 1992, noted ZZ2) applied to the system of linear elasticity, in statics.***

***It comprises 5 modelings in plane constraints, corresponding each one to a type of finite element (TRIA3,***

***QUAD4, TRIA6, QUAD8, QUAD9).***

***The analytical solution is known and makes it possible to compare the errors estimated with the exact error.***

***The interest of the test resides:***

***· in the comparison enters the constraints smoothed with ZZ1 (continuous total smoothing) and ZZ2 (smoothing room with patches of elements),***

***· in the comparison of the estimators between them,***

***· in the qualitative and quantitative analysis of the results (relative errors total and local).***

***The test highlights the good behavior of ZZ2 on all the types of elements and the bad results of ZZ1 on quadratic elements when the solution does not present a strong singularity, which is the case.***

The constraints with the nodes, as a whole, are approximated better with *ZZ2*, especially for the elements *ex*  
\*

of order 2. If one makes tighten  $H$  towards 0, the rates of convergence with  $H$  of  
- are higher by

method *ZZ2* for all the types of elements to those of method *ZZ1* (\* is the smoothed constraint).

Estimator *ZZ1* is not reliable for the elements of order 2, the nodal constraints remain correct. One can  
to check in this particular case that 0 when  $H \rightarrow 0$ , which shows that continuous total smoothing proves  
insufficient to estimate the error in the case of a solution without singularities (case of this test).

*ZZ2* is on the other hand reliable and asymptotically exact (1 when  $H \rightarrow 0$ ).

***SSLV112 - Calculation of G by the method  
Lagrangian for a circular crack***

***Summary***

***It is about a test in statics for a three-dimensional problem. This test allows the calculation of the rate of refund of energy room by the Lagrangian method of propagation for an initial crack quasi-circular plunged in a presumedly infinite medium. One transforms it into circular crack of more important ray.***

***The interest of the test is to study the validity of the calculation of the rate of refund of energy room***

*after extension of  
fissure. It is also to be able to calculate the rate of refund of energy starting from a grid fixed on one  
fissure variable geometry (in elasticity). Methods of calculation of G\_LOCAL, THETA\_LAGRANGE  
and of  
THETA\_LEGENDRE are used.*

*The test includes/understands two modelings.*

**Summaries of the results**

Calculation of G local:

.

2 methods (*THETA\_LEGENDRE* and *THETA\_LAGRANGE*) give the same ones appreciably results (8% of error to the maximum compared to the analytical solution),

.

the precision of the results is average because the extension of the crack is approximately 1.2, which is close to the maximum of extension reasonable for this method for a crack 3D,

.

method *LEGENDRE* is less expensive in time CPU.

**SSLV113 - Estimator of error on a cylinder**

**hollow Bi-materials**

**Summary:**

*This test validates the estimator of error in pure residue, applied to linear elasticity 2D, in statics. One is considered*

*hollow roll made up of two materials and subjected to internal and external pressures.*

*2 modelings are axisymmetric, on quadrangles with 8 nodes.*

*The interest of the test lies in the comparison between the exact and calculated constraints, on the one hand, the error*

*estimated and the exact error, in addition. This test also makes it possible to show the validity of the estimator in residue*

*on a structure bimatérial, contrary to the estimator of Zhu-Zienkiewicz which is not applicable on structures presenting of discontinuities in the stress field (here with the interface material).*

**7**

**Summary of the results**

The estimator of error in residue "ERRE\_ELGA\_NORE" gives good results on the problems in bi-materials.

**Note:**

The estimator of error of Zhu-Zienkiewicz does not give correct results. Indeed, with the interface it detects a strong error because it carries out a continuous smoothing of the constraints whereas it

exists a jump for  $z_z$  and.

**SSLV114 - Movements of solid body 2D and 3D**

**Summary:**

This test validates (in 2D and 3D) key word LIAISON\_SOLIDE of order AFFE\_CHAR\_MECA [U4.25.01].

This key word is used to rigidify an expressing whole of nodes by linear relations that displacements “rigidified” nodes are dependent between them by the equation:

$$\begin{pmatrix} \mathbf{U} \\ \mathbf{M} \end{pmatrix} = \begin{pmatrix} \mathbf{U} \\ \mathbf{U} \end{pmatrix}$$

With + ()

**WITH AMNDT.**

This equation is valid only in small displacements.

The test problem the 2D and the 3D as well as the particular cases:

- geometrically confused nodes (2D and 3D),
- aligned nodes (in 3D).

### **Material properties**

$E = 0$

$= 0$

The finite elements present in this problem are only used to define the ddls carried by the nodes.

Their rigidity must be null.

**1.3**

### **Boundary conditions and loadings**

In this problem, one defines “solid” groups of nodes:

· in 2D:

-

WITH, B, C, D

-

E1, E2, E3

· in 3D:

-

F, G, H, I, J, K, L, M

-

O, NR, P

-

Q1, Q2, Q3

For each one of these groups of nodes, one imposes partial displacements so that them

“solid” move while respecting:

2 .

translation: (

**T**

)

*With* = (

**T E**)

**J. PELLET**

Key:

V3.04.114-A Page:

3/6

Selected displacements forced to lead to required displacements “solid” are:

2D

$DX (A) = 2.$

$DX (E1) = 2.$

$DY (A) = 3.$

$DY (E1) = 3.$

$DY (B) = 3.001$

$(+DRZ (E1) = 0.001 \text{ for modeling B})$

3D

$DX (F, NR, Q1) = 2.$

$DY (F, NR, Q1) = 3.$

$DZ (F, NR, Q1) = 4.$

$DY (J, O) = 2.002$

$DY (J, O) = 2.999$

$DX (I) = 1.997$

$+ DRZ (NR) = 0.003$

for modeling B

$DRX (Q1) = 0.001$

$DRY (Q1) = 0.002$

$DRZ (Q1) = 0.003$

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

The movement of the “solids” being imposed, the reference solution (in displacement) is it imposed movement.

The reference solution is thus exact (in small rotations).

***SSLV115 - Concrete element prestressed in  
compression and gravity***

***Summary:***

***This test allows a simple checking of calculations of gravity for the concrete elements with cables of prestressed, in linear mechanics of the structures static.***

***The concrete element is voluminal, and the elements of cable of prestressing are elements of bar.***

***Only one modeling is used: it makes it possible to test the application of gravity on elements of bar, for two directions of gravity.***

***The values tested are the resultants of the reactions on the supports, equal to the total weight of modeling.***

### ***Summary of the results***

*This test, very simple, makes it possible simultaneously to check the correct operation of gravity in elements of bar of prestressing, which is checked by the perfect coincidence of the results with analytical solution. It was introduced following the discovery D `an anomaly on gravity into bars, and makes it possible to validate the correction.*

**SSLV120 - Stretching of a parallelepiped**

**orthotropic under its own weight**

**Summary:**

*This test of mechanics of the structures allows the evaluation of displacements and the constraints of one parallelepiped becoming deformed under its own weight. The material is elastic linear orthotropic.*

*modeling is three-dimensional. The model is similar to test VPCS SSLV07 (but in this case the material is isotropic) and with test SSLV121 (in this case the material is isotropic transverse).*

*The variations of the results obtained by Aster range between 0,00 and 0,5% of the calculated reference analytically.*

## **Summary of the results**

*The results concerning displacements and the constraints are very close to the solution analytical with adopted modeling ( $< 0.2\%$  for displacements,  $< 0.5\%$  for the constraints).*

*The elastic coefficients in the 3 directions of orthotropism were selected so as to obtain them same values of displacements at the points B, C, D and E that those calculated for a material isotropic (test SSLV007) or isotropic transverse (test SSLV121). Numerically, these values are very close relations of those of these tests at the points considered (of about a  $10^{-6}$ ) the difference resulting from*

*method of construction of the matrices of rigidity in the various cases. As in point X, these values differ but correspond well to the reference solution.*

**SSLV121 - Stretching of an isotropic parallelepiped**

**transverse under its own weight**

**Summary:**

*This test of mechanics of the structures allows the evaluation of displacements and the constraints of one parallelepiped becoming deformed under its own weight. The material is elastic linear isotropic transverse.*

*modeling is three-dimensional. The model is similar to test VPCS SSLV07 (but in this case the material is isotropic) and with test SSLV120 (in this case the material is orthotropic.).*

*The variations of the results obtained by Aster range between 0,00 and 0,2% of the calculated reference analytically.*

### **Summary of the results**

The results concerning displacements and the constraints are very close to the solution analytical with adopted modeling ( $< 0.2\%$  for displacements,  $< 0.5\%$  for the constraints).

The fact that there is only one component of the constraints (zz) in the problem only allows to test 2 elastic coefficients (E\_Z and NU\_Z).

Although these coefficients are constant, they were introduced in the form of functions to test functionality ELAS\_GITR\_FO.

The elastic coefficients in plan XY and direction Z were selected so as to obtain them same values of displacements at the points B, C, D and E that those calculated for a material isotropic (test SSLV07) or orthotropic (test SSLV120). Numerically, these values are very close those of these tests at the points considered (of about a  $10^{-6}$ ) the difference resulting from the mode of construction of the matrices of stiffness in the various cases. As in point X, these values differ but correspond well to the reference solution.

***Handbook of Validation***

***V3.04 booklet: Linear statics of the voluminal structures***

***Document: V3.04.130***

***SSLV130 - Hollow roll into incompressible***

***Summary:***

***This test makes it possible to validate the quasi-incompressible elements in statics for a three-dimensional problem, axisymmetric or two-dimensional (plane deformations). One considers a hollow roll subjected to a pressure intern. The material has a Poisson's ratio equal to 0.4999 and one uses the elements quasi incompressible (modeling INCO). In all the cases of modeling, one carries out the test or not while***

***imposing***

***the condition of perfect incompressibility (DDL\_IMPO and GONF=0)***

***Four modelings are carried out for this problem. Modelings A and B make it possible to test quasi-incompressible modeling 3D (3D\_INCO), on the one hand with HEXA20 (A) and on the other hand with***

***TETRA10 (B). Modelings C and D are studies 2D being based on mixed grids QUAD8 and TRIA6. Modeling C is the study in plane deformations (D\_PLAN\_INCO), modeling D is a study axisymmetric (AXIS\_INCO).***

***This test is similar to test SSLV100.***

***The numerical results are satisfactory for all modelings. The fact of imposing explicitly condition of incompressibility influences only very little the results.***

## **4.5 Remarks**

*The results obtained here are a little worse than in the case of modeling A, but discretization is coarser since there are approximately 2 times less nodes in this case-test. results are satisfactory all the same since the variations are lower than 0.2% for displacements, lower than 0.5% for the deformations and lower than 1% for the constraints. One note again that there is no significant improvement of the result when one imposes explicitly  $tr = 0$ .*

## **6.5 Remarks**

*The precision obtained is very good.*

7

## **Summary of the results**

*With a Poisson's ratio very close to 0.5, one finds the results of the solution analytical incompressible with a weak difference. It is noticed that it is not necessary to impose explicitly the condition of incompressibility  $tr = 0$  to obtain good results since the results are quasi-identical that one activates or not, condition  $GONF=0$  with  $DDL\_IMPO$ .*

### **1** **Problem of reference**

#### **1.1 Geometry**

**The total reference mark is reference mark (A, X, Y, Z). In this reference mark the co-ordinates of the nodes are:**

**To (0. , 0. , 0.)**  
**B (3. , 1. , 0.)**  
**C (2. , 3. , 0.)**  
**D (3.1, - 1)**

**For the 2D, one will study the behavior of the triangle ABC whose material properties are defined in the total reference mark (A, X, y) represented on the figure; this reference mark is turned of an angle of 30° around of Z compared to the total reference mark.**

**For the 3D, one will study the behavior of the tetrahedron ABCD whose material properties are defined in a local reference mark (A, X, y, Z) obtained by rotation of the total reference mark according to angles' nautical (= 30°, = 20°, = 10°).**

**This reference mark is not represented on the figure.**

#### **1.2** **Properties of material**

**The materials used are orthotropic and isotropic transverse.**

**One adopts the convention of terminology used in ASTER, i.e the suffixes L, T and NR means Longitudinal, Transverse and Normal.**

**The units will not be specified.**

### **1.3**

#### ***Boundary conditions and loadings***

*The boundary conditions are of Dirichlet type. One makes the assumption of a field of displacement linear in X and y so that the field of deformation is constant.*

*For the 2D one takes*

$$dX = 2x + 4y$$

$$Dy = 4x + 3y$$

*For the 3D one takes*

$$dX = 2x + 3y + 4z$$

$$Dy = 3x + 5y + 6z$$

$$dZ = 4x + 6y + 7z$$

*For the 2D, one thus will impose:*

.

*for node A*

$$dX = 0, Dy = 0$$

.

*for the node B*

$$dX = 10, Dy = 15$$

.

*for the node C*

$$dX = 16, Dy = 17$$

and for the 3D:

.

for node A

$$dX = 0, Dy = 0, dZ = 0$$

.

for the node B

$$dX = 9, Dy = 14, dZ = 18$$

.

for the node C

$$dX = 13, Dy = 21, dZ = 26$$

.

for the node D

$$dX = 5, Dy = 8, dZ = 11$$

## 2

### **Reference solution**

#### 2.1

##### **Method of calculation**

Calculation is analytical.

One used the formal calculation programme *Mathématica* to carry it out.

One exposes of it the principle only for the 3D.

It is known that the field of displacement is:

$$dX = 2x + 3y + 4z$$

$$Dy = 3x + 5y + 6z$$

$$dZ = 4x + 6y + 7z$$

The field of deformations  $G$  in the total reference mark is thus constant and equal to:

$$2 \ 3 \ 4$$

$$G = 3 \ 5 \ 6$$

$$4 \ 6 \ 7$$

### **3 Modeling**

#### **With**

### **3.1**

#### **Characteristics of modeling**

*Following modelings are implemented:*

.

**2D:**

- *axisymmetric*

- *constraints*

*plane*

- *deformations*

*plane*

.

**3D.**

*For each one of these modelings, one tests materials isotropic transverse and orthotropic.*

*Note:*

*has) The transverse isotropy is not tested for the plane constraints because this case corresponds to isotropy.*

*b) For the axisymmetric case the stress field depends on the point of calculation.*

*This point is selected at the point of integration of the triangle (i.e it is the centre of gravity of the triangle).*

*c) It is pointed out that the orthotropic in an unspecified reference mark is not available for modeling as a Fourier because there is then coupling of all the components of the tensor of constraints: Implementation the current makes it possible to use only the symmetrical components to leave which one can find the antisymmetric components but so that it is possible, it is not necessary that the slips induce tensile stresses.*

## **3.2**

V3.04 booklet: Linear statics of the voluminal structures  
Document: V3.04.134***

***SSLV134 - Fissure circular in infinite medium***

***Summary***

***This test allows, after obtaining the field of displacement by MECA\_STATIQUE, the calculation of the rate of restitution of energy room for a circular crack plunged in a presumedly infinite medium.***

***For the first modeling, only a half space defined by the plan of the crack is represented. Bottom of crack is then a closed curve (a circle) and is defined as such in DEFI\_FOND\_FISS. The rate of restitution room and total is compared with the analytical solution of reference.***

***Three following modelings make it possible to calculate the stress intensity factors  $K1$  and  $K3$ , in 3D and axisymmetric, calculated by POST\_K1\_K2\_K3.***

***Modeling B tests  $K1$  for a grid 3D,***

***Modeling C tests  $K1$  for an axisymmetric grid,***

***Modeling D tests the combination of  $K1$  and  $K3$  for a grid 3D.***

***Lastly, modeling E makes it possible to validate the calculation of the bilinear form of  $G$  on the same problem, and modeling F to validate same calculation for  $G$  local.***

**Problem of reference**

**1.1 Geometry**

**Z**

**= 1.MPa**

**y**

**has**

**X**

**= 1.MPa**

**The crack is circular (penny shaped ace) of ray has, in the Oxy plan. So that the medium is regarded as infinite, the sizes characteristic of the solid mass are about 5 times higher with ray A.**

**1.2**

**Material properties**

**Young modulus:  $E = 2.105 \text{ MPa}$**

**Poisson's ratio:  $= 0.3$**

**1.3**

## ***Boundary conditions and loadings***

### ***Lower face***

***: uniform constraint of traction  $Z = 1$ . MPa***

### ***Higher face***

***: uniform constraint of traction  $Z = 1$ . MPa***

***According to modeling, one also has boundary conditions of symmetry and blocking of movements of rigid body.***

***In the modeling  $D$  where only the quarter of the parallelepiped is represented, one uses conditions with the limits of antisymmetry for the loading of torsion: they amount imposing null them tangential displacements with a face. The loading of torsion is introduced in the form of a force surface tangential (shearing distributed) applied to the lips of the crack.***

### **3.4 Notice**

*One uses key word SYME\_CHAR in operators CALC\_G\_THETA\_T and CALC\_G\_LOCAL\_T for to multiply automatically by two the rate of refund of energy calculated on only one lip of*

*fissure.*

*In the same way in POST\_K1\_K2\_K3, key word SYME\_CHAR allows to calculate the factors of intensity constraints and the rate of refund of energy G\_IRWIN by interpolation of displacements of a single lip of the crack. The displacement of the nodes mediums of the edges of the elements concerning the bottom of crack to the quarter of these edges would allow to improve the precision of calculation.*

### **9.4 Notice**

*The two loading cases (traction and torsion) are taken into account. It is thus necessary to cumulate the values of  $G$  for the two loadings. Moreover, one represents only the quarter of the complete three-dimensional block and thus the quarter of the crack, it is thus necessary to divide the theoretical value of reference of the rate of refund total by 4.*

*Thus*

$$G(S) = (11.586 + 7.356) = 18.943 \text{ J/m}^2$$

$$G = (145.06 + 92.44)/4 = 59.37 \text{ J/m}$$

*Only traction contributes to  $K1$ , only torsion contributes to  $K3$ .*

*[Figure 14.1-a] below shows the values of G local in bottom of crack obtained from bilinear form of G. It is the first loading which is applied (simple traction), it requests it first mode of opening of the crack. The fields as G are discretized according to the method of Lagrange. The rays inferior and superior delimiting the crown in which fields decrease linearly are respectively equal to 0.1 mm and 1mm. The value of reference is equal to 5.79 J/m<sup>2</sup>, cf modeling A.*

## **15 Summaries of the results**

**Objective triple of this test is reached:**

.

**It is a question of validating the definition of the closed funds of crack and installations consequent calculation of G local. One checks in particular the independence of G local with respect to the angle for an axisymmetric crack and a loading. One notes a variation of less than 2% on the whole of the bottom of crack by two methods "LAGRANCE" and "LAGRANGE\_NO\_NO".**

.

**Moreover, this test makes it possible to validate the order POST\_K1\_K2\_K3 which makes it possible to calculate them**

**stress intensity factors by exploiting the jump of displacements on the lips of fissure. This method, less precise than G\_THETA, makes it possible to obtain here (with a grid adapted: nodes mediums of the edges touching the bottom of crack moved with the quarter of these edges) of the values of K1 and K3 to less than 1% of the reference (for the method of extrapolation number 1). With the method of extrapolation number 2, the variation can go up to 8%. Precision of the method of extrapolation number 3, tested in modeling B, lies between those of the two preceding methods. Method 3 is however interesting because it provides a single value of the stress intensity factors and not a maximum value and a minimal value.**

.

**Lastly, one validates the calculation of the bilinear form of G.**

**SSLV135 Damage by tiredness under  
alternate biaxial loading**

**Summary:**

**One presents a test here having an analytical reference [bib1]. The geometry treated here is a cube without defect with which one carries out a linear elastic mechanical calculation followed calculation of the plan of shearing criticizes in each point of Gauss and in each node.**

**Each of four modelings tests a criterion:**

.  
**modeling a: criterion MATAKE;**

.  
**modeling b: criterion DANG\_VAN\_MODI\_AC;**

.  
**modeling C: criterion DOMM\_MAXI;**

.  
**modeling D: criterion DANG\_VAN\_MODI\_AV,**

.  
**modeling E: criterion FATEMI\_SOCIE.**

**The first two criteria are said “to plan of critical shearing”, they are adapted to the loadings periodicals. The last two criteria can be qualified criteria “in plan of critical damage”, they can be used when the loading is not periodical.**

*SSLV139 - Buckling of a circular plate  
subjected to a compressive force uniformly  
distributed on its contour*

**Summary:**

*This test represents a calculation of stability of a circular plate subjected to a compressive force uniformly distributed on its contour. We determine the critical load leading to buckling rubber band of Euler as well as the associated modal deformation.*

*This test validates modeling AXIS\_FOURIER for linear buckling with meshes QUAD8 and TRIA6 (circumferential mode equal to zero), and modeling AXIS with meshes QUAD8.*

*The critical load obtained is compared with an analytical reference solution.*

**Reference solution****2.1****Method of calculation**

The value of the critical load is given in [bib1] by the following expression:

$$F_{cr} = \frac{68}{14} \cdot D$$

$$R$$

with:  $D$  the bending stiffness of the plate (in N.m) defined by the following expression:

$$D = \frac{Eh^3}{12(1-\nu^2)}$$

This critical load is associated a circumferential mode equal to 0.

**2.2****Sizes and results of reference**

For the characteristics given, the critical load is worth:

$$F = 2668.315 \text{ N/m}$$

**2.3****Uncertainties on the solution**

*Analytical solution*

### **Summary of the results**

*The results obtained are very satisfactory for meshes QUAD8 independently of modeling used (AXIS or AXIS\_FOURIER): uncertainties on the critical pressure 0.104% do not exceed.*

*However, it will be noted that modeling AXIS\_FOURIER is definitely less precise with meshes TRIA6 than with meshes QUAD8.*

*This test with licence to test and compare modelings AXIS and AXIS\_FOURIER in buckling linear of Euler of a circular mean structure subjected to an external force of compression uniformly distributed on its contour.*

**SSLV303 - Roll embedded under actual weight and pressure**

**Summary:**

*The goal of the test is to validate a load of gravity as well as a pressure, starting from an analysis 2D with decomposition in Fourier series of the load.*

*Two modelings are adopted for this analysis; they differ from the key word used to define gravity:*

- modeling a: to validate the key word GRAVITY,*
- modeling b: to validate key word FORCE\_INTERNE.*

*Gravity is calculated in mode 1, and the pressure applied is given in mode 1.*

*The two loading cases are combined and compared with a numerical calculation in modeling 3D (model C).*

*The fourth modeling (D) is built with an aim of validating key word FORCE\_INTERNE defined to leave of a function.*

**1.5**

**= U in 3D**

**= ur in AXI**

**Constraints zz**

**NOT B**

**2.8**

**Constraints xx (3D)**

**NOT B**

-14.1

= *rr* (AXI)

**Constraints yy (3D)**

**NOT B**

14.6

= (AXI)

· *The results between modelings 3D on the one hand and AXIS\_FOURIER on the other hand, are concordant with regard to displacements (variation of 1.5%) and the bending stress zz (variation of 2.8%).*

· *A embedding, the relation  $xx = yy = 0$  involves:*

$xx = yy =$

$1 - zz$

*The relation of embedding is well checked at the point B, in modeling 3D.*

· *In addition, at the point B, one has moreover:*

$xx = rr$

$yy =$

*In modeling AXIS\_FOURIER, the difference between the two constraints is approximately 25%.*

· *The second calculation on model AXIS\_FOURIER was carried out with a finer grid: 4 elements in the thickness instead of 2, denser grid in the vicinity of embedding AB (total 800 TRIA6).*

*The variation observed on the constraints *rr* and at point AB remains:  $rr = 1.51 \times 10^6$ ,  $= 2.08 \times 10^6$  (loading case combined).*

*The relation of embedding  $xx = yy$  thus is checked much better on the model 3D, with one grid in the thickness however coarse.*

***3.700 X 105***

***0.***

***A'2, B'2, H'***

***A3, B3, I***

### ***4.2 Remarks***

***· Radial displacement  $ur$  is obtained with a good precision.***

***3***

***· The conditions of symmetry on face AB ( $v = 0$  locally, is  $V_{05} W = 0$ ) are checked***

***2***

***at the points A2, A'2, G, B2, B'2, H, H', I considered.***

***In the same way, the conditions of symmetry on face EF ( $U = U = 0$ ) are checked at the points E2, E'2,***

***F2, F'2, G1, H1, H'1, I1 considered.***

***Key word LIAISON\_OBLIQUE is thus validated.***

***· The identification of the nodes common to the 2 zones by key word LIAISON\_GROUP is also validated: displacements  $U, V, W$  are identical to the points A'2, B'2, H', E'2, F'2, H'1 in comparison of displacements to opposite respective A2, B2, H, E2, F2, H1.***

## 1.3

### **Boundary conditions and loading**

*The model will be limited to the part of the thick disc located in the half space  $Y \geq 0$ , the plan of fissure vertical being a symmetry plane.*

*In the absence of nodes on the axis of revolution, a rigid mode will be blocked by a linear relation between degrees of freedom.*

*That is to say points:*

*With  $(R1,0, T)$  B*

*(- R1,0, T)*

*Blocking of the translation in X:  $UX (A) + UX (B) = 0$*

*Blocking of the translation in Y:  $UY = 0$  in plan XOZ, except for the lips of the crack.*

*Blocking of the translation in Z:  $UZ (A) = 0$*

*Blocking of rotation around OX: ensured by the C.L of symmetry in plan XOZ*

*Blocking of rotation around OY:  $UZ (B) = 0$*

*Blocking of rotation around OZ: ensured by the C.L of symmetry in plan XOZ*

*Loading: stationary angular velocity = 500 radians/second*

### 3.2

#### *Characteristics of the grid*

*The initial grid consists of 8890 nodes and 2203 elements, including 1264 elements CU20 and 939 elements PR15.*

*After the conversion of the grid of quadratic to linear, the number of nodes is reduced to 2230. This conversion is made essential by the use of the operator **DEFI\_FISS\_XFEM**, who function for the moment that with linear elements.*

### 3.3

#### *Functionalities tested*

*Calculation of the factors of intensity of the constraints buildings, in all the nodes of the bottom of crack, by method **THETA**.*

*The factors of intensity of the constraints buildings are calculated on a crown of lower ray  $R_{inf}=0,00075$  m and of ray higher  $R_{sup} = 0,0025$  Mr.*

## 1.2

### *Material properties*

$E = 200.000 \text{ MPa}$

$\nu = 0.3$

$\nu = 0.0$  make it possible to avoid the variation of orthogonal curve induced by the effect Poisson in plates, which causes a difference between the theories of beams and plates, out of average fibre.

## 1.3

### *Boundary conditions and loadings*

· force  $F_y = -1$  (load 1) or couples  $C_z = 1$  (load 2)

· defined or applied to neutral fibre

· embedding of the section  $X = 0$

· continuity of displacements of translation on AB

· continuity of displacements of translation out of C

· equality of displacements of rotation around Z on C1-C2

· for the points M of the section (M1 m2 M4) displacements of translation U (M) depend

linearly displacement of rotation Z of the points P of AB

$U(M) = Z(P) \cdot y + dx(P)$

Reference solution

2.1

Method of calculation used for the reference solution

Analytical solution, isostatic structure.

The elastic arrow, elastic constraints and axial deformations and bending moment in all not X-coordinate X are given by:

· Charge n°1: force  $F_y = 1$

$M_y(X) = F_y \cdot L (1 - x/L)$

(=  $E \cdot I_z \cdot u_y''(X)$  in elasticity)

$u_y(X) = Fy L x^2 (3 - x/L)/(6 E.I_z)$   
(in elasticity)

(in elasticity)

$xx(X, y) = Fy L (1 - x/L) y/(E.I_z)$

(in elasticity)

$xx(X, y) = - Fy L (1 - x/L) y/I_z$

• Charge  $n^{\circ}2$ :  $Cz=1$  or rotation  $drz$  couples =  $Cz.L/(E.I_z)$

$My(X) = Cz$

(=  $E. I_z. u_y''(X)$  in elasticity)

$u_y(X) = Cz. x^2 / (2. E.I_z)$

(in elasticity)

(in elasticity)

$xx(X, y) = Cz. y/I_z$

(in elasticity)

$xx(X, y) = - Cz. y/(E.I_z)$

with:

$L = L1 + L2 + L3 = 30 \text{ mm}$

$I_z = A. h^3/12 = 0.25 \text{ mm}^4$

$drz = 0.0006$

## 8.2 Remarks

The calculation of the efforts and the moment in the Coque\_C\_Plan element is carried out with the node N28 medium

so that the interpolation is correct; knowing that the Young modulus is triple so that the product E. Iz that is to say identical in all the model, the constraints are it too.

### **Summary of the results**

- The grid is very coarse in elements 3D and plate. The test deserves a modeling more fine, since the results are influenced by the way of describing the conditions of embedding out of O. the modeling A led to an error of 14% to the maximum,
- however that with a good taking into account of these conditions, the solution is clearly better (modeling B led to an error of 3% maximum).
- The comparisons of the constraints and efforts give good results (modeling B). For the element of hull 1D, the results are very good.

***Handbook of Validation  
V3.05 booklet: Linear statics of the assembled structures  
Document: V3.05.101***

***SSLX101 - Pipe right modelled in hulls  
and in beams***

***Summary:***

***The purpose of this test is to validate the connection hull-beam. The pipe is embedded at an end, and subjected to 4 successive efforts (traction and 3 moments) on the other end. A half of the pipe is with a grid in hulls, the other is with a grid in beams. Embedding and the connection between the hull part and the beam are carried out by a connection hull-beam, allowing in particular to transmit to the hull only the torque efforts of beam type, without generating secondary stresses.***

***The reference solution is analytical (RDM). The variation with the numerical solution (from 3 to 5%) is explained by fact that the grid in hulls actually consists of element plans (facets). The geometry of the pipe is thus itself approximate. The solution obtained makes it possible to check that connection enters the elements of hull and the element of beam is correct.***

### **Summary of the results**

*The reference solution is analytical (RDM). The variation with the numerical solution (from 3 to 5%) be explained by the fact that the grid in hulls actually consists of plane elements (facets). geometry of the pipe is thus itself approximate. The solution obtained makes it possible to check that it connection between the elements of hull and the element of beam is correct.*

**V3.05.102 document**

**SSLX102 - Piping bent in inflection**

**Summary:**

***This test validates the modeling of the phenomena of ovalization in pipings: an elbow, prolonged by right pipes is subjected to one bending moment. This one causes in the elbow an ovalization which propagate and diminishes in the right parts, and which modifies the rigidity of the whole of piping. For***

***to check the exactitude of the results, one tests the flexibility of the whole of piping (value of displacement with***

***the end for one imposed moment) and elements of hulls DKT.***

***The case test comprises six modelings:***

- For modeling A, the elbow is with a grid in hulls (modeling DKT), modeling pipe is used for the right parts, the connection is ensured by a connection COQUE\_TUYAU.***
- For modelings B and C, modeling PIPE is assigned to the whole of piping: TUYAU\_3M for B and TUYAU\_6M for C (M = modes of Fourier).***
- In modeling D, piping is with a grid in hulls (elements COQUE\_3D), the ends are with a grid in beams to apply the loadings.***
- Modélisation E: Modeling PIPE (3 modes of Fourier) is assigned to the whole of piping.***
- For modeling F, the elbow is with a grid in voluminal meshes, the right parts in elements***

*PIPE and the connection is ensured by a connection 3D\_TUYAU.*

*Modeling A makes it possible to validate the good transmission of ovalization (mode 2) between the elements PIPE, and validates connection COQUE\_TUYAU, two modelings B and C make it possible to validate the elements PIPE (with 3 and 6 modes of Fourier) in linear elasticity and last modeling makes it possible to validate the transmission of ovalization (mode 2) between the elements PIPE, and validates the connection 3D\_TUYAU.*

*15 Summary of the results*

*This test not having reference solutions analytical, but numerical, the variations noted (in on this side 2% except 1 value) can be regarded as reasonable.*

*More precisely, for modeling A (elbow with a grid in hulls DKT and right beams in PIPE) one can estimate that the solution obtained (2.7% of variation in cross-bending, and 0.4% in inflection except plan,*

*compared to the reference: grid all in hulls of modeling D) makes it possible to validate the good operation of connection coque\_tuyau.*

*For modeling B (elements PIPE, 3 modes of Fourier), the important variation on cross-bending*

*(6.8%) is due to the fact that piping is relatively thin, therefore that ovalization in the made elbow to appear of the modes of Fourier of a nature higher than 3.*

*In fact, modeling C (PIPES, 6 modes of Fourier) is very close to the reference (0.01% in cross-bending, and 2% in inflection except plan). The element pipe is thus validated in elasticity for these loadings, compared to a solution in hulls (modeling D).*

*Modeling E (elements PIPE with 4 nodes) gives results identical to modeling B, at a cost of weaker calculation due to a less fine grid.*

**Document: V3.06.100**

**SSLA100 - Infinite cylinder subjected to a field of voluminal and surface forces**

**Summary:**

**This test of linear quasi-static mechanics makes it possible to validate the assignment of a loading of field of forces, surface or voluminal.**

**The studied structure is cylindrical. The fields with the nodes of voluminal and surface density of forces are read in a file with the Ideas format. For the voluminal loading, the field read varies quadratically in function of the distance to the axis; for the surface loading, the field read corresponds to an internal pressure.**

**Three modelings of the same problem are carried out:**

- . modeling 3D;**
- . axisymmetric modeling 2D;**
- . modeling 2D plane deformations;**

**The reference solution is analytical.**

**Problem of reference**

**1.1 Geometry**

**Z**

**y**

**X**

**Selected geometrical dimensions are as follows:**

**.**

**height**

**= 0.5 m;**

**.**

**interior ray**

**= 1 m;**

**.**

**external ray = 1.2 Mr.**

**1.2**

**Properties of material**

**The cylinder consists of a homogeneous material which follows a law of elastic behavior linear:**

**.**

**E = 10 Pa;**

**.**

**= 1 Kg/m<sup>3</sup>;**

**.**

**= 0.3 .**

**1.3**

**Boundary conditions and loadings (cf [Figure 1.3-a])**

*The voluminal force considered is radial, it varies in a quadratic way with the ray:  $FV = .r^2$  with  $= 1 \text{ N/m}^3$ .*

*The surface force considered is applied to the internal wall of the cylinder, perpendicular to wall (is equivalent to an internal pressure imposed on the cylinder):  $FS (R = R_{int}) = 1 \text{ N/m}^2$ .*

*The boundary conditions make it possible to be placed on the assumption of the plane deformations on one*

*section of the cylinder: vertical displacements blocked on the sections high and low of the cylinder.*

*Note:*

*For modeling 3D, the suppression of the clean modes is ensured by the conditions of plane 2D applied to the low section of the cylinder. This type of boundary conditions allows to obtain an axisymmetric in displacement, directly comparable solution with analytical solution.*

**Summary of the results**

*The results obtained by the code\_Aster are very close to the analytical solution, in spite of very coarse grids.*

*Modelings 3D and 2D plane give further information very close because they present them same discretizations circonférencielle and radial. Axisymmetric modeling 2D is more powerful because it presents 2 cuttings in the radial direction and not of discretization circonférencielle.*

**Document: V3.06.103**

**SSLA103 - Calculation of the withdrawal of desiccation and of endogenous withdrawal on a cylinder**

**Summary:**

**The purpose of this case-test is to validate the calculation of the withdrawal of desiccation and the endogenous withdrawal. It also tests possibility of making depend the characteristics materials on the hydration and drying (in the case of it model of Mazars). It is about a cylinder which undergoes a drying and a uniform hydration. The temperature also vary.**

**The cylinder is modelled by four elements quadrangles with 8 nodes for modelings A, C, E and F and by an element HEXA20 for modelings B and D. For modelings A and B, the behavior is presumedly elastic, which makes it possible to validate the calculation of withdrawal at the same time with STAT\_NON\_LINE and with MECA\_STATIQUE. Modelings C and D make it possible to validate the calculation of withdrawal with the law of MAZARS**

*local and not-local (without activation of the damage). Modeling E validates the calculation of withdrawal with law ENDO\_ISOT\_BETON and modeling F coupling ENDO\_ISOT\_BETON/BETON\_UMLV\_FP*

*The results obtained by Code\_Aster are identical to the analytical solution of reference.*

## ***Material properties***

***For modelings A and B, the material is supposed to be elastic and the characteristics materials are constants to be able to validate calculation with MECA\_STATIQUE,***

***For modelings C and D, one uses the law of MAZARS and certain parameters depend on the hydration and of drying.***

***Modeling E makes it possible to test law ENDO\_ISOT\_BETON, and modeling F the coupling ENDO\_ISOT\_BETON/BETON\_UMLV\_FP, knowing that the parameters materials of the law BETON\_UMLV\_FP are selected so that one does not have creep and thus which one finds it behavior of law ENDO\_ISOT\_BETON. In both cases, the characteristics materials are constants.***

***Let us announce that being given the loading (dilation, hydration and free drying), any damage does not develop: one thus finds in all the cases, the elastic solution.***

### ***Summary of the results***

*The results obtained with Code\_Aster are identical to the analytical solution. It was thus validated calculation of thermal dilation and the endogenous withdrawal and desiccation for the elastic model, that it is with STAT\_NON\_LINE or MECA\_STATIQUE, like for the law of Mazars, local version or not-local, for law ENDO\_ISOT\_BETON and the case of the coupling BETON\_UMLV\_FP/ENDO\_ISOT\_BETON. Let us announce that modelings A and B also allow to validate the calculation of the withdrawals for laws VMIS\_ISOT\_TRAC and VMIS\_ISOT\_LINE which uses even routine that ELAS.*

hydrostatic*

*Summary:*

*Case-test DEMO005 is a very simple example of use of Code\_Aster. It makes it possible to illustrate them*

*orders "impossible to circumvent" on the calculation of a tank.*

*The thin cylindrical tank is subjected to a variable pressure with the height corresponding to one hydrostatic pressure.*

*Since the geometry and the loading are axisymmetric, an axisymmetric modeling 2D is chosen to model the problem, the grid representing a vertical section of the cylinder.*

*One calculates displacements and the constraints in the vertical section of the cylinder.*

### 3.3

#### *Command file Aster*

·  
*BEGINNING: obligatory order to start*

•  
***Reading of grid (PRE\_GMSH) and generation of grid (LIRE\_MAILLAGE).***

•  
***Definition of groups of nodes and meshes for the assignment of the loading and of limiting conditions (DEFI\_GROUP).***

•  
***Definition of the finite elements used (AFFE\_MODELE).***  
***One assigns to all the meshes grid modeling AXIS.***

•  
***Definition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU).***  
***The mechanical characteristics are identical on all the structure.***

• ***Affectation of the loading: Definition of a function representing the pressure  $P$  on the face intern of cylinder (DEFI\_FONCTION), then assignment of the pressure on the internal edges cylinder represented by the groups of meshes LDF and LFA (AFFE\_CHAR\_MECA\_F).***

• ***Affectation of the boundary conditions (AFFE\_CHAR\_MECA).***  
***Displacements following there are blocked at the base of the cylinder on the level of the group of meshes SUPPORT.***

•  
***Resolution of the linear elastic problem (MECA\_STATIQUE).***  
***Calculation of displacements and the constraints at the points of Gauss of each element to be left displacements.***

•  
***Calculation of the constraints to the nodes.***  
***One calculates the stress field to the nodes of each element from displacements (CALC\_ELEM).***

•  
***Impression of results (IMPR\_RESU).***  
***One prints in form listing the displacement and the constraints of all the grid.***  
***One also prints the field of displacement to format GMSH, for a visualization results with GMSH.***

•  
***Tests relating to the values of displacements to nodes A, B, C, D. (TEST\_RESU)***  
***These tests make it possible to check nonthe regression of the code.***

***END: obligatory order to close an execution.***

**5**  
**Summary of the results**

**Following displacements  $X$  are relatively important at the base of the cylinder, where the loading is highest. One can note that following displacements there of the high part of the cylinder are negative, which was foreseeable with the sight of the problem.**

Document: V3.90.001

Calculation of an elastic hyperstatic plane gantry

Summary:

The goal of this note is to expose the method of calculation used to determine the reference solution of case-test SLL 14, entitled: "Plane Gantry articulated in foot".

One uses the method of the forces (hyperstaticity 1), by taking account only of the energy of inflection: assumption

slim beams.

One considers four loading cases separately.

### Requests under specific dummy loads out of $C$

In order to calculate displacement out of  $C$ , using the Principle of Virtual work (cf.

paragraph [§8]), it is necessary to establish the diagrams of requests under the action of two “fictitious” forces  $F$  and  $G$  applied out of  $C$ .

**Determination of moment *X* hyperstatic**

One places oneself in elasticity; one considers only the energy of inflection, the beams being slim. The state

naturalness is supposed to be virgin (not prestressings nor of displacement of support).

The complementary potential is then:

(

Recall: in post  $A$   $CI$ : normal effort = -  $GOES$ , shearing action =  $ha$ .

**8****Calculation of displacement out of  $C$** 

One considers also only the elastic energy of inflection (slim beams). By applying the Principle virtual Work on the structure subjected to the fictitious forces of the paragraph [§6], working in sought displacements, one calculates the numbers  $W$  and  $D$  depending linearly on  $F$  and  $G$ :

$$m (M + X M I$$

+

 $Iso$ 

)

 $m (M$  $X M$  $Iso$ 

1)

***TPLA04 - Release of power in one  
hollow roll***

***Summary:***

***This test results from the validation independent of version 3 in linear stationary thermics.***

***It comprises an axisymmetric modeling 2D which tests the axisymmetric elements in thermics, them boundary conditions in imposed temperature and the boundary conditions of the heat source type.***

***This test aims to validate the taking into account of the heat source by comparing the results obtained with those provided by VPCS.***

**Summary of the results**

**The results obtained are satisfactory, the maximum change is 0.63%. Modeling 3D (with meshes PENTA15, HEXA20) and modeling AXIS (with meshes TRIA6) give appreciably same results (the grid and the degree of interpolation are identical).**

**The analytical solution which is an approached solution, supposes that the r/L report/ratio is much higher than**

**1. For this numerical test, the r/L report/ratio was taken equal to 100.**

***TPLA06 - Cylindrical bar with convection***

***Summary:***

***This test results from the validation independent of version 3 in linear stationary thermics.***

***It is about an axisymmetric problem 2D represented by two modelings, the first using of the elements voluminal, the second of the axisymmetric elements 2D.***

***Boundary conditions in imposed temperature and of convection are taken into account.***

***The results resulting from this case test are compared with those provided by VPCS.***

**V4.01.006-A Page:**

**8/8**

**7**

**Summary of the results**

**The modeling A, carried out in 3D with linear meshes (PENTA15, HEXA8), gives results whose four values (out of 22) exceed the tolerance fixed initially. The maximum change obtained is 1.24% for a tolerance of 1%. This going beyond of the tolerance is observed for values of the temperature close to 0.**

**By account modeling B, carried out in AXIS with linear meshes (TRIA3), gives satisfactory results, the maximum change obtained is 0.25%.**

**Modeling AXIS is adapted to model this cylindrical bar than modeling 3D. Cutting circonférenciel in 3D is not enough dense to represent the cylinder, and one finer cutting would improve the results.**

**The results obtained by modeling 3D are regarded as acceptable taking into account grid used.**

**The analytical solution which is an approached solution, supposes that the r/L report/ratio is much higher than**

**1. For this numerical test, the r/L report/ratio was taken equal to 100.**

**Summary:**

***This test results from the validation independent of version 3 in linear stationary thermics.***

***It is about an axisymmetric problem 2D represented by two modelings, the first three-dimensional one, second axisymmetric 2D.***

***The interest of this case test is to test an orthotropic material subjected to various boundary conditions (flow imposed, convection, linear variation of the outside temperatures).***

***The results resulting from this case test are compared with those provided by VPCS.***

## 5 *Summary of the results*

*The results obtained are satisfactory in temperature but far away from the reference solution to level of flows (especially for flow along axis Z). The maximum departures obtained are as follows:*

- 0.212% in temperature,*
- 65.701% for flow along axis Z,*
- -8.205 for flow according to the ray.*

*Flow following the axis: the flow of reference is constant, the variations observed are more important with ends of the cylinder, on the other hand with semi height these variations are very weak (lower than the tolerance).*

*Flow following the ray: The variations according to the ray are higher than the tolerance, but they could to be minimized by increasing the discretization along axis R.*

*Following these results, an anomaly software was emitted under the n° 96-176.*

***Summary of the results***

***The results obtained are very satisfactory, the maximum change is 0.313%.***

***Among the points of observation, the most important variation is noted with the N108 node which belongs to the element more deformed grid.***

***The grid used is that proposed in the reference. A radial grid with the same cutting and with the same meshes should give better results.***

***This test made it possible to test the taking into account of a source term within meshes QUAD9 with one modeling AXIS (AFFE\_CHAR\_THER associated with the key word SOURCE).***

*The condition limits = 0. is implicit on the free edges.*

*Limiting conditions,  $T = -17.778^{\circ}\text{C}$  on KL, and  $T = 4.444$  on, are incompatible at the point L (node n25).*

*Code\_Aster applies a “law of overload” which, in this case, consists in taking into account last condition limits entered. The order of assignment of the imposed temperatures thus has large influence on the results obtained.*

*In the case treated, the temperature on the higher face (IT) is affected after that on the blank of roll (KL).*

### **Summary of the results**

*Modeling gives results whose value (on 10) exceeds the tolerance fixed initially (5%). The maximum change obtained is -6.10%, it is on the smallest value of reference.*

*In this test, Code\_Aster applies a “law of overload” which in this case consists in taking in count the last condition limits entered. The order of assignment of the imposed temperatures, thus has a great influence on the results obtained.*

*Calculations were carried out in °C. Determination of the variation, by considering the temperatures in °F, give a maximum value very different from that obtained in °C.*

*A calculation carried out with software NISA gives identical results has those of Aster (checked in case where the temperature imposed on the point L is of 4.44°C).*

*The quality of the results could be improved by carrying out a finer grid, the problem of overload would be always present, but the zone of influence of the temperature imposed on the point L would be weaker. The results are regarded as acceptable taking into account modeling carried out (grid and system of unit, law of overload).*

*TPLL01 - Infinite plane wall in linear thermics*

*Summary:*

*This case test relates to a calculation of stationary thermics linear. It includes/understands 10 modelings which test them elements 2D and 3D.*

*This case test is of several interests:*

- *for modelings of A with I, it tests on almost all the elements 3D and 2D (except 2D\_AXIS, Lumpés PYRAM and), the calculation of the basic options of linear thermics: “rigidity”, “mass”, exchange, imposed flow, imposed temperature,*
- *in modeling J, one calculates a cartography of space error via option ERTH\_ELEM\_TEMP CALC\_ELEM on which will rest, in a loop PYTHON, the tool of refinement/déraffinement LOBSTER encapsulated in MACR\_ADAP\_MAIL.*
- *The orientation of the wall is unspecified compared to the axes of co-ordinates,*
- *It is one of the rare case-tests to test elements TETRA10 and QUAD9 in linear thermics, with to combine orders AFFE\_CHAR\_THER/LIAISON\_DDL, and to test INTE\_MAIL\_3D.*

**21 Modeling**

**J**

**21.1 Characteristics of modeling**

***It is about a case functional test and of data-processing not-regression of the calculation of the indicator of error has***

***established posteriori in thermics (cf [R4.10.03]). It exhumes a cartography of space error on which will rest, in a loop PYTHON, the tool of refinement/déraffinement LOBSTER encapsulated in MACR\_ADAP\_MAIL (cf [U7.03.01]).***

***The calculation of this chart of indicator of error is carried out, via option “ERTH\_ELEM\_TEMP” of the operator***

***of postprocessing CALC\_ELEM, on a EVOL\_THER (provides to the key word RESULT) coming from one***

***former thermal calculation (linear or not, transient or stationary, isotropic or orthotropic, via THER\_LINEAIRE or THER\_NON\_LINE, cf environment necessary, parameter setting and perimeter***

***of use [R4.10.03] §6.2/4).***

***This calculation requires as a preliminary the recourse to option “FLUX\_ELNO\_TEMP” of CALC\_ELEM which determines***

***values of the vector heat flux to the nodes (cf example of use [R4.10.03] §6.5).***

***The indicator consists of fifteen components per element and for a given moment. In this case test, one calculates the fifteen components but the procedure of refinement/déraffinement does not rest***

***that on the component ERTABS which represents the absolute total space error (cf [R4.10.03] §6.3).***

***In order to be able post-to treat via POST\_RELEVE or GIBI, one needs to extrapolate fields by element in fields with the nodes by element. The addition of option***

***“ERTH\_ELNO\_ELEM” (afterwards***

***the call to “ERTH\_ELEM\_TEMP”) makes it possible to carry out this purely data-processing transformation. For one***

*moment and a given finite element, it does nothing but duplicate the fifteen components of the indicator on each node of the element.*

*This modeling thus constitutes as much an example of use, in a loop PYTHON, possible couplings “calculation of indicator”/“refinement/déraffinement of grid”, that a case test of not-regression of options “ERTH\_ELEM\_TEMP” and “ERTH\_ELNO\_ELEM” and of their adherence*

*with the process of mending of meshes.*

*This case test takes again the characteristics of modeling I and its grid (TETRA10 + TRIA6) associated.*

*antisymmetric*

*Summary:*

*The purpose of this test is to test the model of thermal hull linear with three fields (MODELING: "HULL" or "COQUE\_PLAN") by comparison with an analytical solution, for an infinite plate subjected to one*

*couple stationary antisymmetric heat flows on its two half-faces, in stationary regime.*

*The equation of heat is solved in hover, with a linear, isotropic, homogeneous conduction.*

*Two modelings: With for the finite elements of surface hull (triangles) and B for the linear elements (segments).*

*One simultaneously tests in each modeling the elementary orders and the total order*

*THER\_LINEAIRE [U4.33.01].*

*Handbook of Validation*

**TPLS101 - Infinite plate subjected to an exchange  
symmetrical thermics with outside**

**Summary:**

The purpose of this test is to test the model of thermal hull linear with three fields per comparison with analytical solution, for an infinite plate subjected to a couple of conditions of heat exchange with outside, symmetrical compared to the average layer. The equation of heat is solved in hover, with a linear, isotropic, homogeneous conduction.

The results are presented for the finite elements available of thermal surface hull triangles and quadrangles.

Compared to test TPLS100 [V4.03.100], this one makes it possible to check the contribution of the coefficients of exchange to thermal rigidity, like various methods of assignment of the boundary conditions. Moreover, the solution is such as the temperature is uniform in the thickness.

**Contents of the file results**

- Températures with the nodes of calculation has,
- heat flow on the average layer (calculation has),
- values tested deferred above (calculations has, B, c).

## **5 Modeling**

### **B**

#### **5.1**

### **Characteristics of modeling**

y

N387

X

Cutting:

68 elements in length,

2 elements in width.

Boundary conditions - loading (three calculations for three choices):

- scalar loadings and dualisation of the condition of Dirichlet:

TEMP\_IMPO (NODE: N1, TEMP\_SUP: 0. , TEMP: 0. , TEMP\_INF: 0.)

EXCHANGE: (GROUP\_MA: GRSD1, COEF\_H\_SUP: 10. , COEF\_H\_INF: 10. ,

TEMP\_EXT\_SUP: -50. , TEMP\_EXT\_INF: -50.)  
(GROUP\_MA: GRSD2, COEF\_H\_SUP: 10. , COEF\_H\_INF: 10. ,  
TEMP\_EXT\_SUP: 50. , TEMP\_EXT\_INF: 50.)

· loadings constant functions and dualisation of the condition of Dirichlet:  
as above, but with constant functions having same values.

· scalar loadings and “kinematic” loading:

THER\_IMPO: (NODE: N1,  
TEMP\_SUP: 0. , TEMP: 0. , TEMP\_INF: 0.)

**Summary of the results**

It is noted that the variations on the temperature are weak compared to the reference solution (lower than 0.41%).

Meshs QUAD8 and QUAD9 give the same results.

**V4.03 booklet: Stationary thermics of the plates and the hulls**

**Document: V4.03.302**

**TPLS302 - Distribution of temperature in one thin section**

**Summary:**

One considers a plate subjected to convection applied to the faces lower and higher and one edge of the plate (width). The temperature is imposed on the opposite edge of the plate.

The goal of this test is to validate the thermal element of hull in conduction in the plan and convection

[R3.11.01] and [U1.01.01]. It also makes it possible to validate the elements of edge (THCOSE2, THCOSE3) in convection.

Because of the boundary conditions and loadings considered, the distribution of temperature is uniform along the width. The results are compared with a solution based on a graphic estimate.

two types of approach give equivalent results.

This test results from the validation independent of version 3 in thermics.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

The original reference solution given in the book [bib1] is based on a graphic estimate.

Uncertainty on the solution is unknown.

This reference is quoted in the handbook of checking of ANSYS [bib2].

### 2.2

#### Results of reference

Temperature at the points of co-ordinates  $x/L = 0, 0.1, 0.2, \dots 0.8, 0.9, 1$ .

### 2.3 References

### **Summary of the results**

Results obtained for two modelings (QUAD8 + SEG3 or QUAD + SEG2) in the interval of allowed tolerance ( $< 2\%$  for a tolerance of 5%) which corresponds to uncertainty on results of the graphic estimate of reference.

The data of the test could retain a tolerance of 2%.

## **Summary of the results**

**The results obtained are satisfactory, the maximum change obtained is 0.53%.**

**Modeling 3D used to model this sphere is correct.**

**The quality of the results could be still improved in:**

- carrying out a finer grid of the portion of sphere,**
- choosing quadratic elements for better approximating the reference solution.**

### ***Summary of the results***

***The results obtained are excellent. The computed values by Aster are identical to the values of reference. That is “a normally awaited” result since the field solution which is linear belongs to the space of interpolation of the element tested.***

***This test made it possible to test the following orders:***

- DEFI\_NAPPE allowing to define a variation in the external temperature according to X-coordinate X and of the ordinate y,***
- DEFI\_MATERIAU associated with key word THER\_ORTH, allowing to define the characteristics of one orthotropic material,***
- AFFE\_CARA\_ELEM associated with the MASSIVE key word, allowing to define the axes of orthotropism.***

**TPLV100 - Roll subjected to conditions  
with the nonaxisymmetric limits**

**Summary:**

**It is about a test in stationary thermics with modeling of Fourier.**

**This test validates all the elements of Fourier in thermics (5 different modelings) with various types of boundary conditions: imposed temperature, exchange, imposed flow, heat source.**

**The interest of the test, in addition to the validation of Fourier thermics, lies in the following points:**

- comparison between the results and an analytical solution on various harmonics of Fourier (1, 2 and 3),**
- homogeneity of the elements between them.**

#### **4.2 Remarks**

*The values of flows to the nodes are realised on the elements containing this node.*

*It is noticed that the exact solution is not found. This is with the fact that numerical integration thermal matrix of rigidity is approximate (formula at 3 points of GAUSS). If one were used formulate at 6 points, one would find the solution exactly.*

of exchange between walls in opposite***

**Summary:**

*This elementary test makes it possible to deal with stationary problem in thermics bringing into play two fields separated by imposing a boundary condition of the type exchanges between walls.*

*For modelings presented here, the results obtained by Code\_Aster are identical to the reference calculated analytically.*

## 2 **Reference solution**

### 2.1 **Method of calculation used for the reference solution**

One has a simple analytical solution, since it is about exhiber a harmonic function and to adjust the source associated in each field:

· in field 1:  $T(X, y, Z) = T(1$

With)

2

2

2

+  $X + y + Z$ , (in the reference mark of A1 origin),

1

· in field 2:  $T(X, y, Z) = T(2$

With)

2

2

2

+  $X + y + Z$ , (in the reference mark of origin A

2

2).

One deduces the values from them from  $s1$  and  $s2$ ,  $s1 = 6$  ,  $s2 = 5$ .W/m3.

**1**  
**Problem of reference**

**1.1 Geometry**

**One considers the plane thermal problem of a square cavity (on side equal to 1) where heat propagate:**

- by convection (i.e the particles constituting the medium of the cavity move at a speed  $U$  supposed here constant); speed  $U$  is supposed to form an angle of  $67.5^\circ$  with axis  $X$ ,**
- by conduction.**

**1.2**  
**Material properties**

**One takes  $CP = 1$**

**$10^6$**

**= -**

**from where a diffusivity = = -**

**$10^6$**

**$CP$**

**$U \cdot L$**

**and as one takes  $U =$**

**one has the Peclet number  $p =$**

**= +**

**1**

**$10^6$**

**,**

**E**

*(L is the length characteristic, here  $L = 1$ ).*

**1.3**

*Boundary conditions and loadings*

*On segments AB and BC, one imposes a temperature  $T = 1$ .*

*On segment AE, one imposes a temperature  $T = 0$ .*

*On the 2 other sides, one in the condition by defect, namely, one is with null flow.*

## *locate mobile: simulation of the Varestraint test*

### **Summary:**

*This test presents thermal simulation by finite elements of the Varestraint test. This test of weldability is employed to characterize resistance to the hot cracking of materials.*

*This test makes it possible to test a nonlinear thermal problem formulated in a pointer under condition of stationnarity.*

*In this test only one modeling is carried out, it acts of a thermal modeling PLAN associated with operator THER\_NON\_LINE\_MO allowing to calculate the nonlinear stationary response with one mobile loading.*

**in pointer**

**Summary:**

***This elementary test makes it possible to treat a reducible three-dimensional example with a problem a variable***

***of space in stationary nonlinear thermics in pointer (problem of convection-diffusion).***

***It also makes it possible to check the taking into account of a solid phase shift/liquid by Code\_Aster.***

***The reference solution is analytical and the variations with the results obtained by Code\_Aster are lower***

***to 1%. The problem is modelled in the plane case.***

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

The result of reference is of the semi-analytical type. The equation 1D to be solved is as follows:

$V$

$(T), - KT$

=

$X$

,  $xx$

0

**éq 2.1-1**

with  $(T$

= 0

=

$x=0$ )

$T$  and ( $$

$T x=L$ )

$TL$

by integrating the equation [éq 2.1-1] one obtains:

$$\int \frac{dT}{T} = A$$

**éq 2.1-2**

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

where  $A$  is a constant depending on the boundary conditions, of the report/ratio and of the function

$K$  enthalpy ( $T$ ).

This constant will be analytically given.

The equation [éq 2.1-2] led to:

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

**éq 2.1-3**

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

With +

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

who must check:

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

**éq 2.1-4**

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

WITH + ( $T$ )

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

$$\ln \frac{T}{T_0} = \frac{A}{K} (T - T_0)$$

Knowing  $T_0$ ,  $L$  and  $V$

,  $T$  and ( $T$ )

$0$ ,  $L$

, the equation [éq 2.1-4] must give the value of the constant of integration  $A$ .

However, it is difficult (even impossible) to determine this constant analytically, from where resort to a numerical resolution of the equation [éq 2.1-4] to determine A.

With the facts of the case ( $T, T, T, T, C = C, C \dots$

0  
L  
1  
2  
S  
L  
sl

), we obtained the solution

(physics) of A which takes the value  $A = 294,9117$ .

From this constant, the analytical solution of the problem [éq 2.1-1] is analytical.

**7**

**Summary of the results**

**Two modelings carried out (AXIS\_FOURIER and 3D) give excellent results, the variation maximum is -0.006% for two modelings**

**This test made it possible to test in AXIS\_FOURIER order COMB\_CHAM\_NO with the operands following:**

- COMB\_FOURIER to calculate the temperature in an angle given,**
- COMB\_R to carry out a linear combination of modes 0 and 1.**

***Summary:***

***This test results from the validation independent of version 3 in linear stationary thermics.***

***It is about a problem plane 2D presenting two modelings, one planes, the second voluminal one.***

*The objective is to validate, in the presence of a geometrical singularity, the plane thermal elements and 3D with  
for boundary condition an imposed temperature.*

*The results are compared with those provided by VPCS.*

**Summary of the results**

**Two modelings give results whose certain values exceed the fixed tolerance initially (1%):**

- for modeling A (PLANE with meshes QUAD8), the maximum change is 1.19% (going beyond for only one value out of the 13 tested),**
- for modeling B (3D with meshes HEXA8), the maximum change is 2.7% (going beyond for two values out of 26 tested).**

**The modeling of the geometrical singularity (presence of an important heat gradient close to singularity) is represented better with quadratic elements (modeling A).**

**For two modelings, the precision should be improved by using a finer grid (more important refinement in the zone of the geometrical singularity).**

**The results are regarded as acceptable taking into account modelings carried out.**

## **Summary:**

***This test results from the validation independent of version 3 in linear stationary thermics.***

***It is about a problem plane 2D represented by only one modeling (plane).***

***The functionalities tested are the use of plane thermal elements, of an orthotropic material, three limiting types of conditions:***

***- convection***

***-***

***linear variation of the outside temperatures,***

***- flow***

***imposed.***

***The results are compared with an analytical solution (VPCS).***

## **5** **Summary of the results**

*The results obtained are excellent. The computed values by Aster are identical to the values of reference. That is “a normally awaited” result since the field solution which is linear belongs to the space of interpolation of the element tested.*

*This test made it possible to test the following orders:*

- DEFI\_FONCTION associated with operand NOM\_PARA, allowing to define a variation of outside temperature according to the X-coordinate or of the ordinate,*
- DEFI\_MATERIAU associated with key word THER\_ORTH, allowing to define the characteristics of an orthotropic material,*
- AFFE\_CARA\_ELEM associated with the MASSIVE key word, allowing to define the axes of orthotropism.*

### ***3.4 Remarks***

***Limiting conditions,  $T = 100^{\circ}\text{C}$  on AB, and  $T = 0^{\circ}\text{C}$  on AD, are incompatible at point A. It Code\_Aster applies a “law of overload” which, in this case, consists in taking into account last condition limits entered. The order of assignment of the imposed temperatures thus has large influence on the results obtained.***

***In the treated case, the temperature assigned to point A is of  $0^{\circ}\text{C}$ .***

**Complementary modelings B, C, D, E, F and G**

**Modeling b:**

- Maillage identical to that described in the card of modeling, on 1/8 of the structure, but with quadratic elements,**
- Système of unit (°C, W, m, S).**

**It is noted that the quadratic interpolation improves the results, the maximum change is 49.16% for**

*the value of reference nearest to 0.*

### **Modeling C:**

- *Finer Maillage (22 QUAD8 + 4 TRIA6), on 1/8 of the structure,*
- *Système of unit (°C, W, m, S).*

*It is noted that compared to modeling B, the maximum change does not decrease but increases (54.58%).*

### **Modeling D:**

- *Maillage identical to that described in the card of modeling, on 1/8 of the structure,*
- *Système of English unit (°F, Btu, feet, hr).*

*It is noted that the maximum relative variation decreases in an important way (33.29%), this variation is not more located at the same place. On the other hand it is always located on the value of reference nearest to 0.*

### **Modeling E:**

- *Maillage identical to that described in the card of modeling, on 1/8 of the structure, but with quadratic elements,*
- *Système of English unit (°F, Btu, feet, hr).*

*It is noted that the quadratic elements improve the results by with a linear modeling (maximum change of 6.5%).*

### **Modeling F:**

- *cutting identical to that described in the card of modeling (12 QUAD4) but on 1/4 of the structure,*
- *Système of English unit (°F, Btu, feet, hr).*

*It is noted that this grid with linear elements (without TRIA3) is much more precise, the maximum change is 5.27%.*

### **Modeling G:**

- *Découpage identical to that described in the card of modeling, but on 1/4 of the structure and with quadratic elements,*
- *Système of English unit (°F, Btu, feet, hr).*

*It is noted that this grid (without TRIA3) is much less precise than at the time of modeling F, the maximum change is 6.26%.*

*From these 7 analyses, we can make the following observations:*

- *the grid suggested in the test probe (5 QUAD4 + 2 TRIA3) is not adapted. For to bring closer the reference solution there are two possibilities:*
  - 
  - to use the quadratic grid on 1/8 of the structure,*
  - 
  - to use a linear grid without triangle on 1/4 of the structure,*
- *the choice of the system of unit to important considerable in the calculation of the relative variation,*
- *for same modeling (A) the results between Code\_Aster and NISA are identical.*

## **Summary of the results**

*The modeling carried out on 1/8 of the structure gives results of which many values exceed the tolerance fixed initially (2%). The maximum change obtained is 89%, it is on smaller value of reference. The analysis of the isotherms shows that those are not perpendiculars with right-hand side cd., the condition of symmetry is not observed.*

*To find an explanation to these important differences, several complementary modelings (cf were carried out annexes B). The conclusions are as follows:*

- the change of the system of units ( $^{\circ}\text{C} \rightarrow ^{\circ}\text{F}$ ) makes it possible to decrease the maximum change with one value of 33%,*
- modeling with quadratic elements (and in  $^{\circ}\text{F}$ ) improves the results, the variation maximum is 6.8%,*
- the modeling of one 1/4 of the structure with only of the QUAD4 (and in  $^{\circ}\text{F}$ ) improves them results, the maximum change is 5.27%,*
- the modeling A, carried out with software NISA, gives results identical to those of Code\_Aster.*

*Moreover, it was not possible to get the original reference (delivers of Kreith) quoted in handbook of checking of ANSYS. Method of acquisition of the reference solution and its uncertainty are thus not known.*

*The results are regarded as acceptable taking into account the points evoked above. However it will be necessary to seek complementary elements on the reference solution.*

## **16.2 Remarks**

*At the beginning of transient, one observes slightly different values between the nodes located in a plan  $X = \text{constant}$  ( $< 3$  per 1000). This anomaly seems to be due to modeling in tetrahedrons with 4 nodes. The results remain nevertheless correct compared to the other elements 3D.*
