**TTLL100 - Thermal shock on a plane wall with  
condition of exchange**

**Summary:**

**This test of transitory linear thermics consists in imposing a cold thermal shock on an infinite plane wall on the assistance**

**of a condition limits of exchange. The shock is modelled by a linear slope  $T = 100\text{ °C}$  into 102 S.**

**The problem is dealt with in plan.**

**The reference solution is analytical.**

**The test is carried out on 2 modelings: (TRIA3, QUAD4) and (TRIA6, QUAD9).**

**One tests the algorithm of linear thermics transitory when the matrix of mass is diagonalisée  
(modeling**

**PLAN\_DIAG with ``mass lumping ``).**

## **Summary of the results**

Modeling “PLAN\_DIAG” gives rather satisfactory results. Although the grid comprises few elements in the thickness, the variation on the temperatures remain lower than 3.2%.

Although the thermal shock is brutal, the diagonalisation of the matrix of mass makes it possible to obtain one

solution in temperature which does not oscillate during the transient.

*TTLL301 - Thermal transfer in a bar with  
imposed temperature (sinusoid)*

*Summary:*

*This test results from the validation independent of version 3 in linear transitory thermics.*

*It is about a linear problem 1D represented by two modelings, one planes, the other voluminal one.*

*The functionalities tested are as follows:*

*plane thermal element,*

*voluminal thermal element,*

*transitory algorithm of thermics,  
limiting conditions: sinusoidal variation of the temperature imposed in the course of time.*

*· The interest of the test resides in the taking into account of the variation in the temperature imposed during  
time and of the geometrical discretization.*

*The results are compared with those provided by NAFEMS.*

## **Summary of the results**

*This test is recommended by NAFEMS (but with another type of mesh).*

*Two modelings carried out give the following results:*

- modeling A (PLANE with meshes TRIA3), the maximum change (3.48%) is higher than tolerance fixed initially (2%),*
- modeling B (3D with meshes PENTA15), the maximum change (0.36%) is lower than tolerance fixed initially (2%).*

*The limiting condition is given by using the order “! FORMULATE”. This choice allows good representation of the taking into account of the condition limits of sinusoidal form.*

*Quadratic modeling is adapted to simulate this test. A finer and balanced grid for linear modeling would allow to obtain better results.*

*The results of modeling A are thus regarded as acceptable.*

*The principal interest of this test is its origin: NAFEMS.*

***TTNL02 - Thermal transient with change of phase***

## **Summary:**

*This elementary test makes it possible to deal with one-way problem in non-linear transitory thermics and of to check the taking into account of a liquid/solid phase shift by Code\_Aster while introducing by the intermediary of the voluminal enthalpy latent heat of fusion. The solution is analytical and utilizes functions of erf error and erfc. The problem is dealt with in the plane and voluminal cases.*

*For modelings presented here, the variations of the results obtained by Code\_Aster range between 1 and 4% of the analytically calculated reference.*

***TTNL03 - Thermohydration.***

***Simulation of an adiabatic test***

***Summary:***

***The purpose of this test is to validate the behavior thermo-hydrating THER\_HYDR, by simulating a test***

***adiabat:  
a freshly-mixed concrete sample is plunged in a calorimeter, the catch being carried out with release of heat,  
it is a question of finding the field of temperature and hydration in the course of time.***

***The temperature and the degree of hydration are uniform in the sample. The temperature measured in  
calorimeter will be thus the reference solution, the hydration being determined by analytical  
integration of the law  
of evolution.***

***2 modelings are proposed: three-dimensional and axisymmetric.***

### ***Summary of the results***

*The error obtained compared to the reference solution is about 1% with regard to temperature and the hydration. Let us announce that the problem was dealt with with steps of time of the order*

*from 15 minutes what is relatively small for the phenomenon of hydration which lasts several tens of hours.*

***TTNL302 - Infinite wall subjected to a constant flow  
with variable properties***

***Summary:***

***This test results from the validation independent of version 3 in nonlinear transitory thermics.***

***It is about a linear problem 1D represented by five modelings, one planes, four the other voluminal ones.***

***The functionalities tested are as follows:***

- element of plane thermics,***
- voluminal element of thermics,***
- algorithm of transitory thermics non-linear,***
- variable properties,***
- limiting condition: imposed flow.***

***The interest of the test lies in the taking into account of properties variable (thermal conductivity and***

*heat  
voluminal).*

*The results are compared with an analytical solution.*

## **6.2 Remarks**

*The relative error is to the maximum of 3.95%, except for  $X = 1$  at the moment  $T = 0.1s$  the error is 11%.*

*This error was obtained for the smallest value of the temperature ( $T = 0.004^{\circ}\text{C}$ ). This variation be explained by the fact that the function of error in this point is 0.025347 and that uncertainty on calculation of the function of error is unknown.*

### ***13 Summary of the results***

***Five modelings carried out, have same cutting in the direction of propagation of temperature, they are different only by their type of meshes.***

***Five modelings give results whose certain values exceed the fixed tolerance initially (1%). The maximum change is 9.9%. It appears for the smallest value of reference located in the middle of the wall and at the beginning of the transient.***

***A grid finer associate with a finer temporal discretization should improve quality of results.***

***Moreover, the reference solution utilizes a function of error whose precision is unknown.***

***The results are regarded as acceptable taking into account the points evoked above.***

***This test made it possible to test hexahedral and tetrahedral meshes in non-linear thermics transient as well as the principal following thermal orders:***

- DEFI\_MATERIAU associated with key word THER\_NL, allowing to define the characteristics of one material whose characteristics vary according to the temperature (conductivity and enthalpy),***
- THER\_NON\_LINE orders allowing the resolution of a thermal nonlinear problem stationary or not.***

***TTNL303 - Infinite wall subjected to a jump of  
temperature with variable properties***

***Summary:***

***This test results from the validation independent of version 3 in nonlinear transitory thermics.***

***It is about a linear problem 1D represented by four modelings, two plane and two voluminal.***

***The functionalities tested are as follows:***

- plane thermal element,***
- voluminal thermal element,***
- variable thermal conductivity,***
- non-linear transitory thermal algorithm,***
- limiting conditions: temperature imposed with jump.***

*The interest of the test lies in the taking into account of variable properties in transitory analysis and the variation temperatures imposed according to time.*

## **11 Summary of the results**

**A modeling among four modelings carried out give results of which a value exceed little the tolerance fixed initially (2%). The maximum change is of:**

- 2.013% for modeling PLAN (TRIA6),**
- 1.928% for modeling 3D (PENTA6),**
- 1.913% for modeling 3D (HEXA8),**
- 1.985% for modeling PLAN (TRIA3, QUAD4).**

**It is noted that this variation is whatever the modeling close to 2%, all modelings carried out, have same cutting in the direction of propagation of the temperature.**

**The results obtained are regarded as acceptable for the whole of modelings**

**This test made it possible to test the taking into account of a variable thermal conductivity with a condition limit varying in the course of time.**

**Summary**

***One calculates the linear transitory response thermal or not linear of two plates separated by a play in which is carried out a transfer of heat. The problem is 2D but the boundary conditions make that temperature depends only on the X-coordinate and time. The stationary state is quickly reached, which is calculable analytically.***

***The test makes it possible to check the good taking into account of the terms related to the heat transfer between 2 walls.***

#### Reference solution

### 2.1

#### Method of calculation used for the reference solution

The stationary analytical solution is obtained by solving a null Laplacian on each of both plates of the form  $T(X) = ax + B$ , the 4 coefficients (2 per plate) are obtained by clarifying them boundary conditions:

## Summaries of the results

The enormous difference in computing time between THER\_LINEAIRE and THER\_NON\_LINE is explained in

part by the fact that one had to much more finely discretize the steps of time into nonlinear (3000 between 0 and  $1.5 \cdot 10^5$  S instead of 50 between 0 and  $5 \cdot 10^2$  S) to ensure the convergence of THER\_NON\_LINE.

In addition, the algorithm of Lagrangian increased used in THER\_NON\_LINE is much more expensive than the simple one - method used in THER\_LINEAIRE.

A request for improvement of the performances was deposited.

metal orthotropic**

## ***Summary:***

***This test results from the validation independent of version 3 in linear transitory thermics.***

It is about a problem plane 2D represented by only one modeling (plane).

The functionalities tested are as follows:

- plane thermal element,
- orthotropic material,
- transitory algorithm of thermics,
- limiting condition: convection.

The interest of the test lies in the taking into account of an orthotropic material.

The results are compared with a solution based on a graphic estimate.

### **Summary of the results**

*The results obtained are satisfactory, the maximum change is of 2.5% lower than the fixed tolerance initially (5%) (the reference solution is obtained graphically).*

*This test made it possible to test in linear transient, modeling PLAN, the orders:*

- *DEFI\_MATERIAU associated with key word THER\_ORTH, allowing to define the characteristics of an orthotropic material,*
- *AFFE\_CARA\_ELEM associated with the MASSIVE key word, allowing to define the axes of orthotropism.*

## ***Summary of the results***

***Two modelings give results whose only one value exceeds the fixed tolerance initially. The maximum change is equal to 2.05%, and is thus not very higher than the fixed tolerance (2%). it is located on the smallest value of temperature and for the weakest moment the T (starting of problem).***

***Two modelings, PLAN (TRIA6) and 3D (PENTA15) gives the same results, which is normal since the grid and the degree of interpolation are identical.***

***A finer grid in the zone of the N1 node should improve quality of the results which are regarded as acceptable taking into account modelings carried out.***

#### 2.1

##### *Method of calculation used for the reference solution*

*The reference solution is a numerical solution obtained by the finite element method [bib2] quoted in the reference [bib1]. This solution is based on a network of 168 square elements of 0.05m of dimensioned, with 200 steps of time ( $T = 0.0005$  S).*

#### 2.2

##### *Results of reference*

*Temperature at the points B C D E H and I at the moment  $T = 0.1s$*

#### 2.3

##### *Uncertainty on the solution*

*Unknown factor.*

#### 2.4 References

##### *bibliographical*

### **Summary of the results**

*Modeling carried out (PLANE with meshes QUAD4) gives satisfactory results. The variation maximum is -0.73%, and it is located on the smallest value of reference.*

*The taking into account of the initial condition of type erfc ( $X(2t)$ ) was carried out correctly. It has need the use of order AFFE\_CHAM\_NO allowing to define a field of temperature initial of each node of the model.*

## Summary of the results

Two modelings HULL give results very far away from the reference solution, two anomalies software were emitted under numbers A1 96-144 et al. 96-178.

Modeling PLAN, carried out with meshes QUAD9, gives satisfactory results, the variation maximum obtained is 0.039%.

*TTLP304 - Transfer of heat in a plate*

*orthotropic: imposed flows*

*Summary:*

*This test results from the validation independent of version 3 in linear transitory thermics.*

*It is about a problem plane 2D represented by a modeling (plane).*

*The functionalities tested are as follows:*

- plane thermal element,*
- orthotropic material,*

- *transitory algorithm of thermics,*
- *limiting conditions: imposed flow.*

*The interest of the test lies in the taking into account of an orthotropic material.*

*The results are compared with an analytical solution.*

#### **4.2 Remarks**

*The relative variations are higher than 2% for  $T = 400. \text{ S}$ , inferiors for  $T 600. \text{ S}$*

*On the surface, the results calculated by Code\_Aster are symmetrical compared to the diagonal AC. The maximum variation observed, into relative as in absolute, is 0.29% is 1,4°C, between point A (N291) and the point D (N179) at the moment  $T = 400. \text{ S}$ . These variations decrease in absolute value when time increase.*

## ***10.2 Remarks***

***The relative variations are higher than 2% for T = 400. S, inferiors for T 600. S***

***The results calculated by Code\_Aster on the nodes of external surface are almost identical (maximum: 5.105 °C is 107 into relative).***

## ***11 Summary of the results***

***The results obtained are satisfactory. The maximum change obtained (3%) is on surface external of the sphere for the weakest moment the T. This variation decreases when the moment T increases.***

***Whatever the modeling, the results are increasingly more precise in the center than on the surface external of the sphere.***

***With identical cutting the results between the linear and quadratic elements are appreciably them same.***

**TTLV100 - Thermal shock in a pipe with  
condition of exchange**

**Summary:**

**This test of transitory linear thermics consists in imposing a cold thermal shock on a hollow roll  
presumedly infinite using a limiting condition of exchange.**

**The shock is modelled by a linear slope  $T = 269^{\circ}\text{C}$  into 12 S.**

**The problem is dealt with into axisymmetric.**

**The reference solution is obtained on a fine network.**

**The test is carried out on 2 modelings: (TRIA3, QUAD4) and (TRIA6, QUAD9).**

**One tests the algorithm of linear thermics transitory when the matrix of mass is diagonalisée  
(modeling**

**AXIS\_DIAG with 'mass lumping ').**

### **Summary of the results**

Modeling “AXIS\_DIAG” gives rather satisfactory results. Although grid comprise that 3 elements in the thickness, the variation on the temperatures remains lower than 2.7%. In spite of the violence of the thermal shock, the diagonalisation of the matrix of mass makes it possible to obtain one solution in temperature which does not oscillate during the transient.

with radiation***

***Summary:***

***This elementary test makes it possible to deal with axisymmetric problem in stationary thermics with a condition with the limits of the radiation type. The solution is analytical. The problem is dealt with into axisymmetric and in voluminal.***

***For modelings presented here, the variations of the results obtained by Code\_Aster range between 1 and 2% of the analytically calculated reference.***

## **4.2 Remarks**

*The boundary condition of the radiation type is provided in the form of a function of temperature interpolated linearly between each point (one discretized the curve using 101 here points).*

*Handbook of Validation*

## **Summaries of the results**

*The taking into account of the conditions of radiation is completely correct in this stationary case.*

*Let us note that this test utilized a coefficient of thermal conductivity constant, only*

*non-linearity thus relates to the boundary conditions.*

*The errors are higher on the calculation of flow, which one can explain by the use of*

*smoothings with the nodes, carried out starting from the computed values at the points of integration*

*(points of*

*GAUSS).*

***Handbook of Validation***

***V4.41 booklet: Nonlinear stationary thermics of the axisymmetric structures***

***V4.41.300 document***

***TPNA300 - Tube generating heat with  
variable conductivity***

***Summary:***

***This test results from the validation independent of version 3 in nonlinear stationary thermics.***

***It is about an axisymmetric problem 2D represented by four modelings, two axisymmetric, plane and the voluminal last.***

***The functionalities tested are as follows:***

- axisymmetric thermal element,***
- plane thermal element,***
- voluminal thermal element,***
- variable properties,***
- limiting conditions (imposed temperature, heat source).***

***The interest of the test lies in the taking into account of variable properties and the nonlinear***

***behavior.***

## **11 Summary of the results**

***Four modelings give results whose certain values exceed the fixed tolerance initially (5%):***

- *for modeling A (AXIS: QUAD4, TRIA3), the maximum change is 15,3% and 4 values on 16 exceed the tolerance,*
- *for modeling B (PLANE: QUAD8, TRIA6), the maximum change is 13,8% and 3 values on 24 exceed the tolerance,*
- *for modeling C (3D: HEXA8, PENTA6), the maximum change is 15% and 5 values on 24 exceed the tolerance,*
- *for modeling D (AXIS: QUAD9), the maximum change is 13,7% and 4 values out of 16 exceed the tolerance.*

*These goings beyond of tolerance are observed for values close to 0.*

*Calculations were carried out in °C. Determination of the variation, by considering the temperatures in °F (as in the reference solution), a maximum change very different from that obtained in °C gives (3% instead of 15%).*

*Moreover, it was not possible to get the original reference (delivers of Kreith), quoted in handbook of checking of ANSYS. Method of acquisition the reference solution (estimate graph) and its uncertainty are thus not known.*

*The results are regarded as acceptable taking into account the points evoked above.*

*This test made it possible to test the taking into account a variable thermal conductivity within several modelings. The principal orders tested are as follows:*

- *DEFI\_MATERIAU associated with key word THER\_NL, allowing to define the characteristics of one material whose characteristics vary according to the temperature,*
- *THER\_NON\_LINE orders allowing the resolution of a thermal nonlinear problem stationary or not.*

***Summary:***

*This test results from the validation independent of version 3 in nonlinear stationary thermics.*

*It is about a linear problem 1D represented by two modelings, one planes, the other voluminal one.*

*The functionalities tested are as follows:*

- *plane thermal element,*
- *voluminal thermal element,*
- *limiting conditions: (imposed temperatures, radiation).*

*The interest of the test lies in the taking into account of the radiation.*

*The results are compared with those provided by NAFEMS.*

## **Summary of the results**

*This test is recommended by NAFEMS (but with another type of grid).*

*Two modelings give very satisfactory results, the maximum change obtained is of 0.003%.*

*For modeling PLAN, in spite of the not-symmetry of the grid, one notes that the temperature with nodes (points of observation) pertaining to the TRIA3 and the QUAD4 is identical.*

*The limiting condition of radiation was imposed via a nonlinear loading of flow (flow function temperature). In this test the taking into account of the radiation is completely correct.*

*This test with licence to test order AFFE\_CHAR\_THER\_F (associate with the operand FLUX\_NL which allows to affect a flow non\_linéaire in the case of) modelings PLAN and 3D.*

**Summary of the results**

*The results of reference provided by VPCS are incorrect. New results of reference have summer determined starting from an analytical approach.*

*The results obtained are satisfactory. The maximum change is of:*

- modeling A (3D: HEXA20, PENTA15): 0.026% for the temperature and of 0.076% for flow,*
- modeling B (AXIS: QUAD4, TRIA3): 0.022% for the temperature and of 0.16% for flow.*

*The limiting condition of radiation was imposed via a nonlinear loading of flow (flow function temperature). In this test the taking into account of the radiation is completely correct.*

*This test with licence to test order AFFE\_CHAR\_THER\_F (associate with the operand FLUX\_NL which allows to affect a flow non\_linéaire) in the cases of modeling AXIS and 3D.*

***MTLP100 - Heating and hardening of an infinite bar  
with square section***

***Summary:***

***The purpose of this test is to provide a metallurgy calculation of reference, in postprocessing of an evolutionary calculation of thermics planes linear which one knows the analytical solution. More concretely, this test validates calculations two-dimensional of linear thermics with conditions of exchange and provides values of reference for the austenitic model of transformation to the heating, like for the model of decomposition of austenite with cooling.***

## **5 Modeling**

### **B**

#### **5.1**

#### **Characteristics of modeling**

*In modeling B, one regards the shoe and the plan as two mobile structures. Each structure is then modelled by a node and an element of the type POI1. Node NO2 is supposed blocked, it materializes the plan of friction. One imposes conditions of relations between degrees of freedom with the node NO1 (which models the shoe) so that the movement is one-way in direction.*

**LIAISON\_DDL: (NODE: NO1**

**DDL**

:

(“DX”

“DY”)

**COEF\_MULT**

:

(0.707

-0.707)

**COEF\_IMPO**

:

0.)

*An obstacle of the type BI\_PLAN\_Z (two mobile parallel plans separated by a play) is used for to simulate the slip surface. One chooses to take for generator of this plan axis OY, that is to say*

*NORM\_OBST: (0. , 1. , 0.). By defect, the origin of the obstacle is located at semi distance from the nodes*

*NO1 and NO2. It remains to define parameters DIST\_1 and DIST\_2 which represent the thickness of matter around the nodes of shock.*

*So that there is a force of reaction of the plan on the system it is necessary that this last is slightly inserted in the plane obstacle of a distance  $N$  such as:  $F = K N$*

*$N$*

*$N$ .*

*Like  $F$*

*$Mg$*

*$N =$*

*, one has then  $N = Mg/kN$ .*

*One considered a normal stiffness of shock of 20 N/m (fictitious stiffness which has direction only for to generate a force of reaction of the plan on the system), one thus has  $N = 0,5 Mr$ . Knowing that both nodes NO1 and NO2 are geometrically confused, one chooses for example  $DIST_1 = DIST_2 = N/2$ .*

*Tangential stiffness of shock:  $KT = 400.000 N/m$ : it is large in front of the stiffness of the oscillator so that the phase of stop is modelled correctly.*

## **7 Modeling C**

### **7.1**

#### **Characteristics of modeling**

*This modeling corresponds to the direct transitory response of the rubbing shoe.*

*The normal direction of contact is the local axis X which corresponds in the case test to total axis Z. It slip surface is the local plan (Y, Z) that is to say the plan (X, Y) in the total reference mark. One thus directs the element of shock to a node, with the key word ORIENTATION of operator AFFE\_CARA\_ELEM of following way:*

*ORIENTATION: (MESH: EL1 CARA: "VECT\_X\_Y"  
VALE: (0. 0. -1. 0. 1. 0. ))*

*To be able to obtain a force of reaction of the plan on the system it is necessary that this last is slightly inserted in the plane obstacle of a distance N such as:  $F = K N$*

*N*

*N.*

*The reaction balances the weight of the shoe, one thus has:  $F$*

*Mg*

*N =*

*i.e.  $N = Mg/kN$ .*

*One considered a normal stiffness of shock of 20 N/m (fictitious stiffness which has direction only for to generate a force of reaction of the plan on the system), one thus has  $N = 0,5$  from where  $DIST_1 = 0.5$ .*

*The tangential stiffness of shock considered is  $KT = 400.000$  N/m, the coefficient of Coulomb is worth 0,1.*

*The law of behavior of shock is thus in the following way defined in DEFI\_MATERIAU:*

*DIS\_CONTACT: (RIGI\_NOR: 20.*

*DIST\_1: 0.5*

*RIGI\_TAN: 400000.*

*COULOMB: 0.1)*

*One uses a step of times of 5.104 S for temporal integration.*

## ***Summary of the results***

*The analytical solution of the problem with friction is reproduced with a very good precision (<0.5%). That asks for nevertheless the use of a parameter of tangent stiffness raised enough by report/ratio with the rigidity of the system as well as a step of relatively reduced time of integration. On this example, direct nonlinear calculation is much more expensive in computing times, factor 20, that that on modal basis.*

### **Summary of the results**

*One notes, on the whole of the sizes, a very good agreement with the produced analytical solution.*

*The sizes the least best represented are the duration of shock and the moment of shock (to better than 1%*

*however). This problem is not related on the precision of calculation but to the only fact that a step of time*

*of integration of  $5 \cdot 10^{-4}$  S.A. be selected what over durations as short as 0,03 S produces already one temporal inaccuracy of 1,66%. To supplement this synthesis, one could carry out a test of convergence by decreasing the step of calculation.*

***SDND102 - Seismic response of a system  
mass-arises nonlinear multimedia***

***Summary***

***The problem consists in analyzing the response of a mechanical structure, modelled by two systems mass-arises not deadened, subjected to a seismic loading of harmonic type, with possibility of shock.***

***One tests the discrete element in traction and compression, the calculation of the clean modes and the static modes, it calculation of the transitory response by nonlinear modal recombination of a structure subjected to one accélérogramme (modeling A) as well as the calculation of the direct transitory seismic response of a structure nonlinear (modeling B).***

***This case test is also used to validate a calculation with explicit resolution on accelerations and shock (modeling C) by comparing the results resulting from DYNA\_NON\_LINE and DYNA\_TRAN\_EXPLI.***

***The results obtained are in very good agreement with the results of reference.

## 2 **Reference solution**

### 2.1 **Method of calculation used for the reference solution**

*It is a question of comparing the response of a symmetrical system consisted two systems mass-arises identical to the response of a system mass-arises. Two problems, explained in detail in reference [bib2], are requested by same the accélérogramme.*

*One calculates the Eigen frequencies initially  $f_i$ , the standardized associated clean vectors compared to modal mass  $N_i$  and the static modes of the system (analytical values). One calculate then the generalized response of the system multimedia while solving analytically the integral of Duhamel [bib1]. Lastly, one restores on the physical basis the relative displacement of the nodes of shock what allows us, after having calculated the field of displacements of drive, of to calculate the field of absolute displacements.*

*One calculates the definite function diff as being the difference between absolute displacement of the node shocking on a mobile obstacle and that of the node shocking on a fixed obstacle. It is checked that it is quite null for various moments.*

### 2.2 **Results of reference**

*Displacements relating and absolute to the nodes of shock.*

### 2.3 **Uncertainty on the solution**

*Comparison between two equivalent modelings.*

## **7 Modeling**

**C**

### **7.1**

#### **Characteristics of modeling**

Modeling C is before a whole test of DYNA\_TRAN\_EXPLI, whose results are compared with DYNA\_NON\_LINE.

The systems mass-arises are modelled, as in modeling A, by a discrete element with 3 degrees of freedom DIS\_T. Only modeling with a degree of freedom is tested.

#### **Modeling of the problem:**

Y

Play

dist\_1

K

m

NO1

NO2

1

elm1

#### **Appear 7.1-a: Modeling of a system mass-arises impacting a rigid wall**

Node NO1 is subjected to an imposed acceleration 1 (T). One calculates the relative displacement of the node

NO2, its displacement of drive and its absolute displacement.

An element of the type DIST\_T on a mesh POI1 is retained to simulate the impact of the beam on one rigid wall: the possible shocks between the beam and the obstacle are taken into account as being

forces intern with this element. One affects to him a nonlinear behavior of type shock (stiffness) via law of behavior DIS\_CONTACT of order DEFI\_MATERIAU.

The thickness of matter surrounding the node of shock in the direction considered is specified by operand DIST\_1 of order DEFI\_MATERIAU. In the treated case, one chooses  $DIST_1 = 0.4495$  and  $PLAY = 0.45$  so that at the initial moment, the node of shock and the obstacle are separated from the play  $J = 5.104$  mm (cf [Figure 5.1-a]).

The seismic loading, due to imposed displacements of node NO1, is calculated by the operator CALC\_CHAR\_SEISME. One creates then a concept charges starting from operand VECT\_ASSE of order AFFE\_CHAR\_MECA.

One uses the diagram of integration of explicit NEWMARK of type DIFFERENCES CENTREES with a step of times of 103 S. calculation by DYNA\_TRAN\_EXPLI is carried out in modal space, non-linearity being due to the shock and thus resident local.

## 7.2

### Characteristics of the grid

The grid associated with the model consists of 2 nodes, of a mesh SEG2 of the type DIS\_T and one specific mesh POI1 of the type DIS\_T.

## 9

### Summary of the results

The results obtained with *Code\_Aster* are in conformity with those awaited (error lower than thousandths).

On this example, direct nonlinear calculation is much more expensive in computing times, of one factor 20, that that on modal basis.

Modeling C shows that one obtains many similar results with a method of explicit temporal integration (DYNA\_TRAN\_EXPLI) and implicit (DYNA\_NON\_LINE).

***V5.01.104 document***

***SDND104 - Calculation of the power of wear of one mass rubbing under seismic excitation harmonic***

***Summary:***

***One considers a mass in contact rubbing with a rigid plan on which one imposes a vibratory movement of harmonic type. Friction is modelled by the law of Coulomb. The calculation of the response of the mass is of nonlinear transitory type. One calculates the power of wear resulting from the phases of slip between mass and the rigid plan. The calculation of the power of wear being developed in Aster only for calculations modal, the analysis is carried out on the basis of modal system (commonplace). In order to avoid the numerical problems resulting from the nullity of the single mode of rigid body of the mass, a spring far from stiff is introduced, flexible mass at a point interdependent of the vibrating rigid plan.***

***The reference solution is a quasi analytical calculation of the transitory answer, of which estimates numerical are programmed with Maple.***

***Single Aster modeling retained tests the explicit algorithms of integration with constant step of Euler (order 1) and Devogeleare (order 4), as well as the algorithm with variable step ADAPT (order 2) developed in order DYNA\_TRAN\_MODAL, for various amplitudes of the harmonic acceleration of excitation***

*seismic of the rigid plan of support. According to this amplitude, the mode of the response of the mass is of the type member for any time (stick), successively member and slipping (stick-slip), or always slipping with inversion of the direction of slip (slipway-slipway).*

*Account is returned owing to the fact that in the case of a sufficiently low amplitude of excitation (first mode, permanent adherence), the power of wear is strictly null.*

*Problem of reference*

*1.1 Geometry*

*The system considered consists of a simple heavy mass posed on a rigid support subjected to an imposed vibration of type seismic, sinusoidal. The contact, as well as solid friction are modelled by penalization. The system thus has two degrees of freedom of translation (horizontal and vertical).*

*RZ*

*RY*

*M*

*X-ray*

*F*

*A very weak spring of stiffness connects the mass to the support in the three directions. This spring is one artifice of calculation, intended to avoid the nullity of the frequency associated with the rigid mode with translation horizontal of the mass. Fascinating the Aster results account the presence of this spring are little different from the results which one would obtain without spring.*

## 1.2

### *Properties of the model*

*Stiffness of the spring (according to the three directions):*

*$K = 3.10^{-5} \text{ N/m}$ ,*

*mass:*

*$m = 1 \text{ kg}$ ,*

*gravity:*

*$G = 10 \text{ m/s}^2$*

*coefficient of Coulomb:*

*$\mu = 0,1$ .*

## 1.3

### *Boundary conditions, conditions initial and loadings*

*The mass rests on the rigid level with the dimension  $Z = 0$ .*

*The harmonic acceleration imposed on the base has as an equation  $a = a \sin (T$*

*).* In particular, it is

*0*

*null at the initial moment. The displacement of the support satisfies equation  $X (T) = - (A/2$*

*)  $\sin (T$*

*), and*

*0*

*thus its movement starts towards the left, with nonnull initial speed &*

*$X ()$*

*$0 = - a$  has/.*

*0*

*The initial displacement (with  $T = 0$ ) of the mass is taken null. The mass is regarded as in state of adherence at the initial moment. It thus has same nonnull speed as the support with  $T = 0$ .*

*Calculations are carried out for various values of maximum acceleration:*

*$a = 15 \text{ m/s}^2$  has,  $a = 15$*

*,  $a = 10 \text{ m/s}^2$ , has  $a = 10$*

**Reference solution**

**The reference solution, which is analytical, is calculated in the following way.**

**That is to say  $X(T)$  the X-coordinate of the mass in the fixed reference mark and  $X(T)$  the X-coordinate of the vibrating support in it even reference mark.**

**Initially, it is supposed that the mass is adherent on its support. It then remains to it certain time after the initial moment  $T = 0$ . It undergoes of this fact the acceleration imposed by the rigid support, that is to say**

**&**

**$X(T) = \&X(T) = \text{has } \sin T$**

**. The tangential force exerted by the mass on the support is then**

**0**

**$F = -mx\&(T) = -my \sin T$**

*(null at the moment initial, which justifies the starting assumption*

*T*

*has**has**Time  $T$  satisfies equation  $X T$*  *$= X T$ , is  $\mu g (T - T)$* *0**-* *$\cos T$* *0**= -* *$\cos T$ , or**2**& ()**2**& ()**2**2**1**1**2**still  $(T - T) - cost + cost = 0$ .**2**1**1**2**This equation, transcendent, allows the determination of  $T$  according to  $T$  and, that is to say finally,**2**1**taking into account the expression of  $T$ , the determination of  $T$  according to the physical parameters of**1**2**system and. If the acceleration of the support in  $T$  is lower in absolute value than  $\mu g$ , it**2**movement remains adherent then up to one moment  $T$  for which the acceleration of the support and of**3**mass reach the value  $-\mu g$ , moment which for reasons of clear symmetries on graphs  $C_i$  above, exactly satisfied  $T = T \pm$ . The mass starts a phase of slip then*

3

1

*up to one moment  $T$ , after which the movement reproduces periodically.*

4

*It is understood that for sufficiently small values of, the movement will not be able to become member as from time  $T$ , because the acceleration of the mass would exceed the threshold  $\mu g$ . There thus exists*

2

*a value criticizes  $*$  such as for  $> *$ , the movement of the mass passes without phase of adherence of a slip to a shift in opposite meaning. A reflexion on the continuity of function response of speed of the mass compared to the parameter shows that for  $*$ , it later movement is always slipping (mode of “slipway-slipway”, of alternate directions). For  $< *$ , it movement periodically alternates phases of adherence and slip.*

*The value criticizes  $*$  admits a simple analytical expression. Indeed, for  $= *$ , the moments  $T$*

2

*and*

*$T$  are confused. Thus  $T - T = T - T$  =/and the equation*

The Aster solution considered is the calculation of the power of average wear during a phase going transient from 4 to 11,99 seconds (from 8 to 24). The energy of wear for this length of time transient differs somewhat from the energy of average wear (asymptotic) over this duration (such an amount of in

situation of stick-slip that of slipway-slipway). It is thus appropriate, to precisely compare it with the results

Aster, to make an exact calculation of this energy in the interval of time [4s, 11,99s].

For  $A = 15 \text{ m/s}^2$ , the power of average wear asymptotic is 15,1146144886 Watt then

0

*that the power of average wear on the temporal interval [4s, 11,99s] is 15,257521794 Watt. It is this last value which constitutes the result of reference.*

*Note:*

*As a calculation of average power, power of wear calculated on an interval is not obligatorily increasing with the duration of the interval. If one adds to the interval one duration over which there is adherence, the power of average wear will be lower.*

### **3 Modeling**

**With**

#### **3.1**

#### **Characteristics of modeling**

*An element of the type DIS\_T on a mesh POIL is used to model the system.*

*Calculation is done on modal basis. One blocks displacements in Y and Z, the modal base thus contains that a mode.*

*One uses the dynamic operator of calculation on modal basis DYNA\_TRAN\_MODAL, with the key word SHOCK to model nonthe local linearity.*

*An obstacle of the type PLAN\_Z (two parallel plans separated by a play) is used to simulate the plan of slip. One chooses to take for generator of this plan OY is NORM\_OBST: (0. , 1. , 0.).*

*The origin of the obstacle is ORIG\_OBST: (0. , 0. , 1.), its play which gives the half-spacing between plans is 0.5.*

*One places oneself in the relative reference mark (loading mono-support) and one applies a loading in acceleration with CALC\_CHAR\_SEISME.*

*One uses a step of times of 3.105 S for temporal integration to limit the computing time. It no time is quite lower than min (2/K/M, 2/K/M*

4

)

10

.

7

-

=

S

NR

.

*The tangential stiffness of friction is taken as large as possible to ensure the stability of diagram, is  $KT = 900000 \text{ N/m}$ . the value  $KT = 1000000 \text{ N/m}$  led to a numerical instability. Normal stiffness  $kN$  must be taken equal to  $20 \text{ N/m}$  to compensate for the weight exactly of mass. (the value of the play is of  $0,50\text{m}$ ). Any other value leads to aberrant results.*

## 5 *Summary of the results*

*The case-test validates the calculation of the power of wear with POST\_DYNA\_MODA\_T after a*

*calculation on*

*DYNA\_TRAN\_MODAL, as well on a diagram with variable steps (ADAPT) as on diagrams with step constant (Euler and Devoggeleare). In particular the tangential microphone-speeds induced by model of contact by penalization, at the time of the phases of adherence, are correctly cancelled.*

*The influence of the added spring remains in on this side precise details obtained.*

*The tangential stiffness of the contact is the element limiting for a higher precision. Convergence results towards the reference solution was checked. The tangential stiffness was taken too large that possible to ensure the stability of the diagram with  $dt = 104 \text{ S}$ .*

*The tolerances in the tests-resu are taken just above the found differences.*

2

**Reference solution**

2.1

**Method of calculation used for the reference solution****Analytical resolution for the uniform mode**

For the uniform mode, the differential equation governing the movement of stop of the mass is written

2

X

X

the following way:  $MX$

= +

X

X

By integrating once the differential equation, one obtains an expression the speed of the projectile in function of its position:

2

2

X

0 +

X

X = -

X

where

0

X

0

X +

=  $M$ 

While integrating once again compared to time this differential equation it comes:

2

1

X

X

1

$$1$$

$$T =$$

$$0$$

$$X$$

$$0$$

$$2$$

$$0 - X +$$

$$2$$

$$\text{Log}$$

$$X$$

$$\cdot$$

$$0 X 0 +$$

$$X +$$

$$-$$

$$X X 0$$

***Numerical resolution for the streamline flow***  
*The dynamic equation to which this system is subjected is as follows:*

$$2$$

$$X$$

$$X$$

$$X$$

$$MX$$

$$= + +$$

$$X$$

$$X$$

$$X^3$$

*This equation cannot be solved in an analytical way, one uses a resolution by a diagram of integration temporal of the dynamic problem. One can rewrite the system in the form:*

2  
 $X$   
 $X$   
 $M -$   
 $X$   
 $T$   
 $T$   
 $= +$

$X$   
 $T$   
  
 $X$   
 $X^3$   
 $T$   
 $T$   
 $T$

*One uses the diagram of Euler modified to integrate this equation in time.*

$X, X$   
 $0$   
 $0$  given to  $t_0$ ,  
 To repeat:

### **3 Modeling**

#### **With**

#### **3.1**

##### **Characteristics of modeling**

*The springs are modelled by discrete elements with 2 ddl DIS\_T.*

*Mass 2 is isolated of its position of balance of a distance from 1 mm at null initial speed.*

*An obstacle of the type BI\_PLAN\_Z is retained to simulate the impact between the two masses.*

*In DYNA\_TRAN\_MODAL, the normal rigidity of shock was selected very high (2.88 10<sup>10</sup> N/m) in order to take into account only the effect of the fluid blade. Two methods of calculation “ADAPT” and “EULER” were tested. Calculation is launched on 1 second with a step of time of 10<sup>-5</sup> second and a step of filing of 100. Syntax used is presented below.*

*tran\_ge1 = DYNA\_TRAN\_MODAL (MASS\_GENE: massegen RIGI\_GENE: rigidgen*

*METHOD: “ADAPT” %OU “EULER”*  
*AMOR\_REDUIT: (0.0.0.0)*

### **Results of modeling**

#### **4.1**

##### **Values tested of modeling**

One calculates the response of the system over one duration of 1 second. One compares then the results with

those resulting from Matlab calculation in some points which correspond to some extremum of the evolution

displacement. On the figures which follow, the results resulting from Aster are in continuous feature and those

calculated with matlab in features dotted lines.

Results obtained with method ADAPT:

***SDND120 - Transitory response of a device  
antiseismic***

***Summary***

*An antiseismic device was tested on a mobile plate. This case test aims to reproduce numerically this test. The device is modelled by two systems mass-arises not deadened, separate by nona linearity of the antiseismic device type.*

*One tests the discrete element in traction and compression, the calculation of the clean modes, the static modes and it calculation of the transitory response by nonlinear modal recombination of the structure subjected to one accélérogramme. Nonthe linearity is of type ANTI\_SISM.*

*The result of reference is a program MATLAB.*

*The results obtained are in very good agreement with the results of reference.*

*One also compares the results calculated with the efforts and displacements measured on a device experimental (qualitative comparison only).*

*Handbook of Validation*

*V5.01 booklet: Nonlinear dynamics of the discrete systems*

*HT-62/01/012/A*

*1*

*Problem of reference*

*1.1 Geometry*

*An antiseismic device is placed between two jaws (right-angled hatched on the following figure) themselves posed on a mobile plate subjected to an acceleration imposed in direction X. It by nona linearity of the type “antiseismic device” placed on both sides one is modelled*

*system mass-arises.*

*X*

*D*

*B*

*Antiseismic device*

*Y*

*F measured in A*

*C*

## *1.2*

*Material properties*

*The jaws which insert the device are modelled each one by a system mass-arises:*

*stiffness of connection:  $K = 1010 \text{ N/m}$ ;*

*specific mass:  $m = 25 \text{ kg}$ .*

*The device tested is an antiseismic device of BULGE type. Its characteristics are them following:*

*.  
 $K1 = 6. 106 \text{ N/m (RIGI\_K1)}$ ,*

*.  
 $K2 = 0,53 106 \text{ N/m (RIGI\_K2)}$ ,*

*.  
 $Py = 1200 \text{ (SEUIL\_FX)}$ ,*

*.  
 $C = 0,07 105 \text{ (C)}$ ,*

*.  
 $\alpha = 0,2 \text{ (PUIS\_ALPHA)}$ ,*

*.  
 $xmax = 0,03 \text{ m (DX\_MAX)}$ .*

## *1.3*

*Boundary conditions and loadings*

*Boundary conditions*

*Only authorized displacements are the translations according to axis X. the points C and D are embedded:  $dx = Dy = dz = 0$ . The other points are free in translation according to dx:  $Dy = dz = 0$ .*

*Loading*

*The point D is subjected to a transverse acceleration in the direction X  $1(T) = 0,66 \sin(T) \text{ m/s}^2$  with  $= 2$ , the point C is fixed.*

#### **1.4 Conditions initial**

*At the initial moment, the device is at rest: with  $T = 0$ ,  $dx(0) = 0$ ,  $dx/dt(0) = 0$  in any point.*

***SDNL32 - Impact of a girder hinged on elastic support***

**Summary:**

*This problem corresponds to a transitory analysis by modal superposition of a non-linear system made up*

*of a flexible beam rotulée with one of its ends. It is animated of a rotational movement of body solid at the initial moment and meets an elastic thrust with unilateral contact. The problem has one reference solution suggested by Commission VPCS.*

*There is a modeling with elements POU\_D\_T. Operator DYNA\_TRAN\_MODAL [U4.54.03] is tested. variations with the reference solution do not exceed 0.8%.*

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

The reference solution was established by commission VPCS.

One refers for the moment with results communicated by J.P. TEASES (Central School of Lyon) using code ANSYS, as well as the code PLEXUS of the ECA.

The solution is calculated for an analysis in small displacements.

**2.2**

**Summary of the results**

One really notes in concord with the this and reference solution (1.2%) in spite of the presence of a non-linearity of shock and the use of a method of modal recombination with 1 base modal reduced to 10 modes. The strongest difference is observed for the non-linear thrust more stiff.

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

The period  $T$  of a mobile pendulum without friction around the point fixes O, whose mass is concentrated in the centre of gravity G ( $OG = L$ ) and whose maximum angular amplitude is 0 is given by the series [bib1]:

$2n$

$L$

$T = 2$

$1 +$

$2$

$has$

$0$

$\sin$

$G$

$N$

$2$

$n = 1$

with

$2 N - 1$

*has* =

*N*

*2 N*

## 2.2

### Results of reference

For  $L = 0.5$  m,  $G = 9.81$  m/s<sup>2</sup> and  $\theta = \pi/2$ , one finds:  $T = 1.6744$  S

## 2.3

### Uncertainty on the solution

One summoned the terms of the series until  $N = 12$  inclusively, the last term taken into account being lower than  $10^{-5}$  times the calculated sum.

**5**

**Summary of the results**

One sees on this case-test that temporal integration by the “rule of the trapezoid” of Newmark does not modify that very slightly the frequency and does not bring parasitic damping, since at the end of one period one returns to very little close with the initial position.

***SDNL104 - Under-structuring transitory***

***nonlinear: shock of a beam on 1 support***

***Summary:***

***The applicability of this test relates to the dynamics of the structures, and more particularly the calculation of***

*nonlinear transitory response by dynamic under-structuring.*

*It is a question of calculating the nonlinear transitory response of a beam in inflection with shock on an elastic support and*

*subjected to a constant force as from the initial moment. The beam is modelled by elements of the type POU\_D\_E (model beam of Euler).*

*The results of reference result from a direct transitory calculation by modal recombination. This test allows*

*thus to validate the computational tools of response transitory per under-structuring, in the case of the catch in*

*count non-linearities of the shock type on a fixed obstacle.*

## **5 Modeling**

### **B**

#### **5.1**

#### **Characteristics of modeling**

The beam is cut out in 2 parts of equal size. Each substructure considered is with a grid in segments to which are affected of the elements of the type “POU\_D\_E”.

=

+

The structure is studied using the method of under-structuring with interfaces of the type “Craig-Bampton” (blocked interfaces).

The base of the first 5 clean modes of the complete structure is calculated by under-structuring.

Then, the transitory problem, projected on this basis, is solved by the transitory operator of calculation by modal recombination (DYNA\_TRAN\_MODAL).

## 6.2 Remarks

In the case of a nonlinear transitory calculation, it is not abnormal to obtain uncertainties important on not realised sizes. The variation from 6 to 8% between the reference solution and solution obtained by under-structuring for acceleration thus does not invalidate the method tested, more especially as the results in displacements are excellent (variation < 0.1%).

### **Summary of the results**

The precision on displacements of the loose lead of the beam at the moment  $T = 1$ . S is excellent (relative error  $< 0.1\%$ ).

This test thus validates the operators of non-linear transitory calculation by dynamic under-structuring. The values of acceleration with the diagram of Devogelaere are to be analyzed.

**SDNL105 - Under-structuring transitory**

**nonlinear: shock of 3 beams between them**

### **Summary:**

The applicability of this test relates to the dynamics of the structures, and more particularly the calculation of

nonlinear transitory response by dynamic under-structuring.

It is a question of calculating the nonlinear transitory response of 3 beams in inflection with shocks to the center of the beams.

The beams are modelled by elements of the type "POU\_D\_E" (model of Euler).

The results of reference result from a direct transitory calculation by modal recombination. This test

allows

thus to validate the computational tools of response transitory per under-structuring, in the case of the catch in

count non-linearities of the shock type between mobile structures.

## **5 Modeling**

**B**

### **5.1**

#### **Characteristics of modeling**

=

X 3

The dynamic under-structuring makes it possible to calculate the vibratory behavior of the 3 beams to be left

dynamic characteristics of only one beam. This one is with a grid in segments to which are affected elements of the type “POU\_D\_E”.

The structure is studied using the method of under-structuring with interfaces of the type “Craig-Bampton” (blocked interfaces).

The base of the first 15 clean modes of the complete structure is calculated by under-structuring.

Then the transitory problem, projected on this basis, is solved by the transitory operator of calculation by modal recombination (DYNA\_TRAN\_MODAL).

*SDNL111 - Impact of two beams*

*Summary:*

*This problem is a problem of impact of two beams in traction and compression. A first free beam is animated an initial speed parallel with the axis of the two beams and comes to run up against one embedded second against its base. Non-linearity comes from the conditions of contact between the two structures. This test comprises a solution analytical of reference.*

*Initially, one uses a transitory analysis by modal recombination of a non-linear system constituted of structures of beams (modelings has and b).*

*The beams are discretized by finite elements of type POU\_D\_T. Operators DEFI\_OBSTACLE [U4.44.21] and DYNA\_TRAN\_MODAL [U4.53.21] are tested. The variations with the values of*

**reference do not exceed  
not 4.5%.**

**In the second time, one makes a direct calculation on physical basis, with elements 3D (modelings C, D and E). The operators tested are: DYNA\_NON\_LINE, AFFE\_CHAR\_MECA/CONTACT with the methods CONSTRAINT, LAGRANGE and CONTINUOUS.**

## ***Summary of the results***

*For modelings has and B (with DYNA\_TRAN\_MODAL):*

*The precision of calculation is relatively average what is due to the choice of the coefficients of penalization used to model the contact. The increase in the stiffness of contact improves considerably the field of displacement but generates the important oscillations of the field of speed around the analytical solution.*

*For modelings C, D and E (with DYNA\_NON\_LINE):*

*The precision of calculation is very good (4% of maximum change). In this case, three methods used results of comparable quality give. For this size of problem, the computing time is more length with the method CONTINUES.*

*SDNL111 - Impact of two beams*

*Summary:*

*This problem is a problem of impact of two beams in traction and compression. A first free beam is animated an initial speed parallel with the axis of the two beams and comes to run up against one embedded second against its base. Non-linearity comes from the conditions of contact between the two structures. This test*

*comprises a solution  
analytical of reference.*

*Initially, one uses a transitory analysis by modal recombination of a non-linear system  
constituted of structures of beams (modelings has and b).*

*The beams are discretized by finite elements of type POU\_D\_T. Operators DEFI\_OBSTACLE  
[U4.44.21] and DYNA\_TRAN\_MODAL [U4.53.21] are tested. The variations with the values of  
reference do not exceed  
not 4.5%.*

*In the second time, one makes a direct calculation on physical basis, with elements 3D (modelings C,  
D  
and E). The operators tested are: DYNA\_NON\_LINE, AFFE\_CHAR\_MECA/CONTACT with the  
methods  
CONSTRAINT, LAGRANGE and CONTINUOUS.*

## ***Summary of the results***

*For modelings has and B (with DYNA\_TRAN\_MODAL):*

*The precision of calculation is relatively average what is due to the choice of the coefficients of penalization used to model the contact. The increase in the stiffness of contact improves considerably the field of displacement but generates the important oscillations of the field of speed around the analytical solution.*

*For modelings C, D and E (with DYNA\_NON\_LINE):*

*The precision of calculation is very good (4% of maximum change). In this case, three methods used results of comparable quality give. For this size of problem, the computing time is more length with the method CONTINUES.*

*Moreover, for modeling C, one also tested two types of diagrams of integration in time implicit: modified average acceleration (key word HHT with option MODI\_EQUI='NON': option by defect) and “complete” HHT (key word HHT with option MODI\_EQUI='OUI').*

*With “complete” diagram HHT, the maximum variation observed with the reference solution drops slightly: 2,15% against 3,73% with the modified average acceleration. Other values tested are impacted very little, with the choice of values of the parameter of the diagrams employed in it case-test (= -0,1 for the modified average acceleration and = -0,3 for HHT).*

*SDNL130 - Seismic response of a beam in  
reinforced concrete (rectangular section) with behavior  
nonlinear*

## **Summary:**

*The problem consists in analyzing the seismic response of a concrete beam reinforced via one modeling beam multifibre [R3.08.08]. The behavior of the beam BA is nonlinear. The concrete is modelled with the law of behavior of Borderie in its version 1D [R7.01.07].*

**Appear 4th: Curve reaction-arrow for the 3 first second**

One carries out tests of results (TEST\_RESU) for the reaction on the first support and the arrow with center. One tests these values for some extremums in the 3 first second of seism, i.e. in the neighbourhoods of times 1,75s (any beginning of the nonlinear field), then 2,04s, 2,68s and 2,87s when the structure is already strongly damaged.

**Note:**

*To have a case test not consuming unnecessarily time CPU, only the 3 first seconds of seism are tested.*

It is noted that the differences in effort in the nonlinear field are very weak, whereas there is an unquestionable difference for displacements. This difference is doubtless due to the effects damping which exploits a great part displacements.

**SDNV100 - Impact of a beam on a rigid wall**

**Summary**

**This problem corresponds to a direct transitory analysis of a non-linear system modelled in elements**

**voluminal. A first slim structure (beam) of square section is animated an initial speed and comes to run up against a rigid wall. Non-linearity comes from the conditions of contact between the structure and the wall. This test comprise a reference solution and a modeling.**

### ***Reference solution***

***2.1***

#### ***Method of calculation***

*The reference solution comes from [bib1]. They are explicit axisymmetric calculations carried out with various codes. One is unaware of almost all modeling: presence of contact, presence of friction, coefficient of friction? In this measurement, one uses this reference in manner indicative. The other tests will be of nonregression.*

### ***Summary of the results***

*Present modelings differ from the reference of the literature by the taking into account from not*

*additional linearities (contact, friction), which explains the differences between their results respective.*

*It is also noted that calculation 3D presents a overcost of enormous time CPU compared to the axisymetry, which is explained at the same time by the greatest number of degrees of freedom but also by treatment of the friction which is much more complex in 3D than in 2D.*

## ***SDNV104 - Dynamic response of a rubbing shoe rigid subjected to a pressure and a force of recall***

### ***Summary***

***One considers a mass in contact rubbing with a rigid plan. It is retained by a spring and one imposes to him a side pressure. Friction is modelled by the law of Coulomb. Calculation is a dynamic calculation direct.***

***The reference solution is analytical.***

***Modelings suggested use DYNA\_NON\_LINE with an elastic law of behavior in 2D, for two solveurs. The contact is managed by various methods available in AFFE\_CHAR\_MECA.***

### ***Problem of reference***

#### ***1.1 Geometry***

*The system considered consists of a shoe: square of 1m on 1m, posed on a support. It is subjected with its weight, with the force of recall of a spring of stiffness  $K$  and with a side pressure. The contact is one rubbing contact.*

$K$

$m$

PTAN

$y$

$X$

## **1.2**

### ***Properties of the model***

Mass:

7.103 kg

Stiffness of the spring:

24.103 N/m

Coefficient of Coulomb:

0,3

*Gravity:*

*70.000 Pa*

*Side pressure:*

*200.000 Pa*

*Young modulus of the shoe:*

*2,1. 1011 Pa*

*Young modulus of the solid mass:*

*1,0. 1011 Pa*

*Poisson's ratio:*

*0*

## **1.3**

### ***Boundary conditions, conditions initial and loadings***

*The mass rests on the rigid level with the dimension  $X = 0$ .*

*The loadings of weight and side pressure are applied with a slope which reaches sound maximum in 0,07 second.*

*The support is embedded in X and Y.*

## **2**

### ***Reference solution***

*The reference solution is analytical.*

*If one regards the shoe as sufficiently stiff not vibrating (rigid movement of body), there is an analytical solution with the problem.*

*One can then write the equation of the movement as follows:*

$$m \ddot{x} + K X = T$$

$$F \pm F$$

$$F = \mu N$$

$$F$$

$$K$$

*One notes: =*

$$m$$

**Stage 1:**

$$X$$

$$m \ddot{x} + kx = F - F$$

*with a X-coordinate and a null speed. One has then:*

$$F - F$$

$$X(T) =$$

$$1$$

$$(-\cos(\omega t))$$

$$K$$

*this result is valid as long as  $x \neq 0$ , i.e. until  $T =$ .*

$$F - F$$

*The first extremum of curve  $X(T)$  is  $X =$ .*

$$2$$

$$1$$

$$\cdot$$

$$K$$

**Stage 2:**

$$X$$

$$m \ddot{x} + kx = F + F$$

*the initial X-coordinate is worth 1*

*X, and speed is null. One has then, by posing the new X-coordinate of times with/:*

$$F + F$$

$$F - 3 F$$

$$X (T) =$$

$$+$$

$$\cos (.t), \text{ until } T. =.$$

$$K$$

$$K$$

$$4 F$$

The second extremum of curve  $X (T)$  is  $x_2 =$

$$.$$

$$K$$

**Stage N:**

One separates the movement according to the sign speed.

One obtains in a general way:

$$2 p -1$$

$$($$

$$2 Ft - (2 p -)$$

$$1 F)$$

$$PF$$

$$x_2 p \ 1$$

$$- T =$$

$$T =$$

$$x_2 p = (T = Pt) \ 2$$

$$.$$

$$2$$

$$,$$

$$2$$

$$K$$

$$K$$

$$K$$

with

$$2$$

$$T =$$

$$\text{and} =$$

$$.$$

*m*

*F*

*F*

*F*

*F*

*The stop of the movement occurs when X*

*T -*

*T +*

*N is included/understood enters*

### **13 Summary of the results**

**The results obtained on the whole of this case test are satisfactory, as well into linear in quadratic. The values obtained are with less than 1% from/to each other; and less than 4% of reference solution.**

**It is noted that the value of reference of the second point is lower than the two others, which increase the percentage of error artificially.**

**The choice of the coefficients of the penalized method is delicate. But it is noted that once them coefficients chosen, the result is stable with respect to the choice of the finite elements and the solvor.**

***Problem of reference***

***1.1 Geometry***

***One considers a cube on side length 2 m subjected to a uniform traction according to the direction vertical Z:***

***Z***

***Y***

***X***

***For reasons of symmetry, one will consider only one eighth of the structure, which will be with a grid by one only cubic linear voluminal element.***

***1.2***

***Properties of material***

***The structure is supposed to be homogeneous, composed of an isotropic elastoplastic material, with work hardening isotropic linear:***

- $E = 2 \times 10^4 \text{ MPa}$***
- $\nu = 0.49999$***
- $\rho = 7900 \text{ kg/m}^3$***
- $\sigma_y = 0,1 \text{ Mpa}$  (elastic threshold SY)***
- $D_{\text{AND}} = 200 \text{ Mpa}$  (tangent module plastic D\_SIGM\_EPSI)***

***One thus chooses a material which remains always almost incompressible, that one is in mode rubber band or plastic. Moreover, one imposes a relationship 100 between the elastic stiffness and the stiffness plastic tangent.***

## **1.3**

### **Boundary conditions**

*One imposes a uniform loading of traction type imposed according to Z on the higher face of the cube.*

*This force imposed, initially null, grows linearly with time.*

*The other boundary conditions are of Dirichlet type and translate the conditions of symmetries of problem (according to the 3 orthogonal plans (xOy), (xOz) and (yOz)).*

*These boundary conditions are sufficient to block all the movements of rigid body of system.*

## **1.4 Conditions**

### **initial**

*The first calculation being quasistatic, one imposes just an initial displacement no one.*

### **Handbook of Validation**

**3/4**

## **2**

### **Reference solution**

## **2.1**

### **Method of calculation**

*One wants to check two types of quantities:*

- *the first critical load buckling,*
- *the first Eigen frequency of the system in vibration.*

*The value of reference of the critical load required is obtained by a quasistatic calculation (word key CRIT\_FLAMB of STAT\_NON\_LINE). One takes this value obtained with the last step of calculation*

*quasistatic, which corresponds at the moment  $T = 1$  S.*

*The number stored under CHAR\_CRIT in the structure of data result (it is the coefficient minimal multiplier of the loading forced to obtain the buckling load) being proportional with the imposed loading which is monotonous growing linearly with time, one corrects it to have the true value at the first moment of transitory dynamic calculation, is 1,001 S.*

*One has, by definition of multiplying coefficient CHAR\_CRIT:*

*F*

*= TANK \_ CRIT T F T*

*critical*

*(I) ext. (I)*

*The external force is proportional to time:  $F T = F T$ , therefore  $F$*

*= TANK \_ CRIT T F T.*

*critical*

*(I)*

*ext. (I)*

*ext.*

*I*

*ext.*

*I*

*The assumption is made that on a step, the loading evolves/moves very slowly and thus that one can to compare the result of dynamic calculation to a quasistatic evolution during this step. One can then to write, for the first dynamic step, which follows quasistatic calculation:*

*F*

*= TANK \_ CRIT*

*T F T TANK CRIT*

*T*

*F T*

*critical*

*STAT \_ NOT \_ LINE (I)*

*—*

*ext.*

*I*

*DYNA \_ NOT \_ LINE (I 1*

*+ )*

*ext.*

*I 1*

*+*

***I***  
***—***  
***T***  
***,***  
***1 001***  
***I I***  
***+***

***For the vibratory analysis, one will make two tests:***

- ***by using the elastic matrix of stiffness,***
- ***by using the matrix of tangent stiffness plastic.***

***The two values of reference are obtained by two linear modal calculations carried out with operator MODE\_ITER\_SIMULT.***

***To obtain the first Eigen frequency corresponding to the elastic case, one makes an elastic design linear with definite initial Young MODE\_ITER\_SIMULT and material above (of being worth modulus***

***2.104 Mpa).***

***To obtain the first Eigen frequency corresponding to the tangent plastic case, a calculation is made linear rubber band with MODE\_ITER\_SIMULT and a fictitious elastic material of which the Young modulus***

***is worth the definite plastic tangent module above: 200 Mpa, is 100 times less than the module real rubber band. One will thus have an Eigen frequency 10 times weaker than the preceding one.***

***One knows also the analytical solution of our problem (cubic length 1 made up of only one linear finite element) which is brought back to a case 1D of traction compression:***

(kg/m<sup>3</sup>)  
- 4.0 E11 1000 0.3***

***Table 1.2-1: Linear mechanical characteristics of material.***

***These linear characteristics are assigned to the first two sub-models. The third under model also has these characteristics as well as characteristics of behavior linear isotropic plastic with a plastic module of 4.0 E10 Pa beyond of a limit of constraint from 80 MPa.***

### ***1.3 Boundary conditions and loadings mechanical***

***The beam is embedded at the left of sub-model 1 and free end at the right end of under model 3. For the calculation of the clean modes of each substructure as well as static modes connections between substructures 1 and 2d' a share, 2 and 3d' another share, one also embed with level of these connections.***

***The excitation of the structure is carried out by applying at the right end P3 of sub-model 3 one force sinusoidal traction in time in the horizontal direction X of frequency 50 Hz and of modulate 100 MNewtons.***

**Instruction manual****V5.03 booklet: Nonlinear dynamics of the voluminal structures****HT-62/06/005/A****Code\_Aster ®****Version****8.3****Titrate:****SDNV107 - Plastic beam in dynamically condensed traction) Date****29/08/2006****Author (S):****G. DEVESA Key****:****V5.03.107-A Page:****3/6****2****Reference solution****2.1****Method of calculation used for the reference solution**

**The field of modelled calculation includes/understands a nonlinear field of calculation I and one series of**

**external linear fields with calculation E which will be condensed dynamically. Here field I is it sub-model 3 and the fields E are sub-models 1 and 2.**

**The matrices M, C, K, the forces F can break up into a part associated with the field I and one part associated with (X) the field (S) E. balance of the structure of total displacement X by**

**DYNA\_TRAN\_EXPLI can be written then:**

$$(SEMI + ME) X'' = F_{Iext} + FE_{ext} F_{Iint} KE X - (C_i + EC) X'$$

**[1]**

**That is to say a modal base of Ritz orthogonalized by elementary under-structuring on the whole of fields I and E. One uses the transform of Ritz then:  $X = Q$  and thus while projecting [1] per T with left one obtains:**

$$(SEMI + ME) Q'' = T F_{Iext} + FE_{ext} T (F_{Iint} + C_i X') - KE Q - EC q'$$

**[2]**

**tiny room to I becomes and X reduced to I thus becomes X [2] becomes for each step of time:**

$$M Q'' = T F_{Iext} T (F_{Iint} + C_i x') + FE_{ext} - KE Q - EC q'$$

**[3]**

**One thus needs the generalized matrices M diagonal as well as full matrices KE and EC and**

*vector generalized FEext which takes part under the terms complementary to the reduced standard problem*

*with I and solved without dynamic condensation by DYNA\_TRAN\_EXPLI:*

$$M \ddot{Q} = T F_{\text{ext}} T (F_{\text{int}} + C_i \dot{x})$$

*With each step of time, one evaluates and adds the complementary terms resulting from condensation dynamics with those of the standard problem without dynamic condensation and one solves in manner*

*traditional in generalized co-ordinates Q. The knowledge of the modal base of Ritz orthogonalized will then allow to obtain at the same time X on the under-field of resolution and X on the whole of under fields.*

*SDNS01 - Nonparametric probabilistic model -  
parametric of a flexbeam with not  
localised linearities of shock*

*Summary:*

*This case-test relates to the nonparametric and parametric probabilistic models of uncertainties in linear dynamics with possibly of nonthe localised linearities. The mechanical model used is one rectangular plate with an elastic thrust of shock. Random generators of matrices and variables random (operators GENE\_MATR\_ALEA and GENE\_VARI\_ALEA) are tested and validated in this*

*case test.*

*statistical postprocessings (CALC\_FONCTION) are also tested.*

*This case-test has two modelings. The first uses a damping proportional. The second use a definite reduced damping by key word CALC\_AMOR\_GENE of COMB\_MATR\_ASSE testing thus this functionality.*

**Boundary conditions and loadings**

**The flexbeam is in simple on 3 edges and free support on its 4th edge GOLD. Degrees of freedoms blocked are thus:**

- on COp and QR, displacements according to  $X1, X2, X3$  and rotations according to  $X1, X3$ .**
- on PQ, displacements according to  $X1, X2, X3$  and rotations according to  $X2, X3$ .**
- on GOLD, displacements according to  $X1, X2$ .**

**The plate is subjected to a vertical impulse load  $E(T)$  on 9 nodes of the plate according to  $X3$  direction. The loading  $E(T)$  is such as, for  $t < 0$  and  $t > 2t1$ ,  $E(T) = 0$  and for  $0 \leq t \leq t1$ :**

**$E(T) = ((T-T1)) \cdot \sin \{(C/2) (T-T1)\} - \sin \{(C/2) (T-T1)\}$ .**

**with  $t1 = 2, = 2 \times 40 \text{ rad/s}$ ,  $C = 2 \times 20 \text{ rad/s}$ .**

*The energy of the function  $E(T)$  is mainly distributed in the frequential band  $[0,60]$  Hz, which contains 8 elastic modes of the linearized dynamic system.*

## **1.4 Conditions initial**

*The dynamic system is initially at rest.*

## **2 Reference solution**

### **2.1 Method of calculation used for the reference solution**

*We study the transitory response of a nonlinear dynamic system subjected to a load impulse determinist due to a shock on the structure. Nonthe linearity of the system is due to one butted elastic of high rigidity comprising a certain play. Spectra of frequency response standardized are used in order to study the transitory response of this system. Equations of dynamics are discretized by the method with the finite elements. The grid of the structure is supposed sufficient fine to collect all the dynamic phenomena of this mechanical system in term of field of displacement for the impulse loading considered. Random uncertainties of dynamic system are modelled by using the nonparametric probabilistic model uncertainties. Consequently, the transitory answer is a nonstationary stochastic process whose statistical estimates are evaluated.  
The results of reference are given in the form of graphs in the article referred below, consultable on <http://www.resonance-pub.com>.*

## ***3 Modeling***

***With***

### ***3.1***

***Characteristics of modeling***

***Modeling: DKT***

***The average model with the finite elements of the plate consists of a regular rectangular grid whose step is constant and is worth 0.01m in the directions X1 and X2. There are thus 41 nodes in width and 51 nodes in the length. Consequently, all the finite elements are identical and each one is an element plates with 4 nodes. This average model finite elements comprises 2000 elements***

***stop and  $m=6009$  degrees of freedom, by counting only the translations in Z and rotations according to X1 and X2).***

***Eigen frequencies of the dynamic system linearized (the plate without the thrusts of shock but with the concentrated masses and stiffnesses) are  $f1=1.94$ ,  $f2=10.28$ ,  $f3=15.47$ , ...,  $f8=53.5$ ,  $f9=66.1$ ,  $f10=68.9$ , ...,  $f30=198.3$ ,  $f31=206.0$ ,  $f32=208.9$ , ...,  $f50=330.9$ ,  $f51=336.3$ , ...,  $f100=670.8$ ,  $f120=817.6\text{Hz}$ .***

***Modeling: DIS\_T***

***The concentrated masses and the concentrated stiffness are modelled by elements DIST\_T.***

***Damping***

***The matrix of damping [D] of the model average finite element is defined as being one linear combination of the average matrices finite elements of mass [M] and stiffness [K]. One thus***

*has*  
*[D] = a [M] + B [K] with*

*2maxmin*  
*2*

*has =*  
*and*  
*B =*

*,*  
*max + min*  
*max + min*

*where =0.04, min=4 rad/s and min=200 rad/s.*

*Small-scale model and ddl observed*

*For this case test, the model finite elements is projected on the first 5 elastic modes of structure linearized, which constitutes the data of the model reduces average. It should be noted that 5 first modes are not enough to obtain convergence compared to the number of modes (cf paragraph Comments of the Results of modelings).*

*The degree of freedom observed is the D.D.L jstop corresponding to displacement in translation according to Z of node or are the elastic thrusts. It is the node of co-ordinates (0.31, 0, 0). The spectrum of response standardized for this D.D.L is built for a band of frequential analysis J=2 [1, 100] rad/s and of which the frequential resolution is of 0.5Hz.*

*Achievements of the random matrices of the parametric nonparametric probabilistic model*

*The matrices of masses, stiffnesses and dissipation of the model reduces average are replaced by achievements of the random matrices of mass, stiffnesses and of dissipation according to the model nonparametric probabilist. For that, we use the generator of random matrices GENE\_MATR\_ALEA. At the time of the first call to this generator, key word INIT must take the value "YES" in order to initialize the generator of random variable of uniform law of Python. Thereafter, INIT will be able to take its default value (INIT= 'NON'). The initialization of the generator of random variable of Python is to be done only one and only once by study, in theory, except if the user wishes explicitly to re-use the same random pseudo sequence.*

**:**

**V5.06.001-A Page:**

**5/8**

*The level of dispersion of the random matrices of the nonparametric probabilistic model is controlled by a parameter of dispersion fixed at 20% (=0.2). The key word DELTA thus takes value 0.2.*

*Lastly, for each pulling of the random matrices of mass, stiffness and dissipation, it is necessary to inform the corresponding average matrix of the model reduces average via the key word MATR\_MOYEN.*

*The stiffness of shock is it also made random due to uncertainties. To build a realization stiffness of shock following a law gamma, we use random generator GENE\_VARI\_ALEA with key word TYPE= 'GAMMA'. We suppose that the possible whole of the values for achievements of the random stiffness of shock is the interval  $[0, + [$ , that the average value of the unit achievements of the stiffnesses of shock corresponds to the stiffness of shock of the average model finite elements.*

*The level of dispersion of the achievements of the stiffness of shock is controlled by a parameter 'fixed at 1% (=0.01). The key word DELTA thus takes value 0.01.*

*Resolution of the probabilistic nonlinear dynamic system.*

*Operator DYNA\_TRAN\_MODAL is used to build the transitory response of the dynamic system nonlinear for each realization of the random stiffness of random shock and the matrices of mass, of stiffness and dissipation. It should be noted that we carry out for this case test only ns=5 achievements of each random variable (stiffness of shock + matrices) what corresponds to 5 iteration of method of digital simulation of Monte Carlo (cf paragraph Comments of the Results of modelings).*

*The temporal interval of the study is  $T = [0,4]$  S, with a step of 5. 105 S. the diagram of integration temporal selected is EULER.*

*Construction of the statistical estimates.*

*After each call to DYNATRAN\_MODAL, we have a realization of the process stochastic of generalized displacements. It is thus possible to build acceleration with the node of shock following the D.D.L jstop by operator RECU\_FONCTION. The spectrum of answer standardized is then built by operator CALC\_FONCTION.*

*These two operations are classically carried out at the time of deterministic studies and give us here a realization of the stochastic process of the spectrum of answer standardized. It is then about to build statistical estimates of the NS achievements of this last. Estimates considered in this case test are the envelopes min and max as well as the average and the moment of order two of standardized spectra of answer. With each pulling (iteration of Monte Carlo) we build these estimates with the assistance only of operator CALC\_FONCTION and the key words WRAPS, POWER and COMB. At the end of the NS iterations of Monte Carlo, we have the estimates required statistics relating to the stochastic process of the spectrum of answers standardized. Finally L2 of the average normalizes is calculated by the key word NORMALIZES of operator CALC\_FONCTION. Interest to evaluate such a standard is to allow studies of convergence according to the number of modes of model reduces average random and according to the iteration count of the numerical method of Goes up Carlo. This standard is calculated here to check that the functionality goes, but convergence is not not reached to save time CPU.*

## **4.2 Comments**

*The various statistical estimates are not converged here. Only 5 simulations of Monte Carlo were made. One would have needed 700 at least of them. Moreover, it is necessary to increase the number of modes with 50 to obtain the convergence of the model projected in the frequency band considered. Calculations being then too long for a case test, we preferred to voluntarily degenerate them two convergences after validation of those on a complete study. After convergence, them statistical estimates calculated starting from Aster correspond very exactly to the results given by the standard commodity.*

### **Summary of the results**

The precision necessary for this test was fixed at 0.5% instead of 0.1% not not to lengthen time too much of calculation. However, one checks that by refining the discretization in time, the error made compared to

the reference solution tends towards zero.

***Handbook of Validation***

***V6.01 booklet: Nonlinear statics into axisymmetric***

***V6.01.100 document***

***SSNA100 - Tube of Bree: Method Zarka-Rack  
(ZAC)***

***Summary:***

***This test of nonlinear quasi-static mechanics consists in modelling an infinite cylinder subjected to a pressure intern and a variation in temperature in the thickness depending recurringly on time (tube of BREE). behavior is elastoplastic with a criterion of Von Mises and a linear kinematic work hardening. One validate the simplified method thus Zarka-Rack (ZAC) into axisymmetric for a radial loading in a case of adaptation ( $T=30^{\circ}\text{C}$ ) then in a case of accommodation ( $T=120^{\circ}\text{C}$ ). This method is a postprocessing realized by order POST\_ZAC [U4.83.21]. For more details one will refer to the document [R7.06.01]. Two modelings make it possible to test the method in 2D and 3D:***

- in modeling a: the cylinder is modelled by axisymmetric elements 2D (QUAD8),***
- in modeling b: the cylinder is modelled in 3D (meshs HEXA20).***

***The results obtained by Code\_Aster are very close to the reference solution.***

## **7** ***Summary of the results***

*It appears at the end of this test that the results obtained are in concord with the solutions of reference. However, in the case of the adaptation ( $T=30^{\circ}\text{C}$ ) projection starting from an initial state corresponding to the preliminary calculation of an elastoplastic semi-cycle is necessary to approach accurately solutions. Contrary, the case of accommodation ( $T=120^{\circ}\text{C}$ ) has already results correctly approximate starting from an initial state no one.*

*One will find in [bib1] and [bib2] of other results relating to this test like incremental calculation realized with COCAINE or numerical solutions obtained with programmed method ZAC in the INCA code.*

**Summary of the results**

*The results are satisfactory taking into account the diversity of the origin of the reference solution. Although the two algorithms of contact give identical results in displacement and in force, returned effective surfaces of contact differ slightly. Sights respective natures*

*of the two algorithms, that is completely comprehensible. To obtain the same ones exactly results, it is necessary to make calculations in 10 steps of time.  
Lastly, the difference in time CPU between the two algorithms is explained by the more significant number  
iterations of Newton carried out by the algorithm algocp.f (METHOD: "LAGRANGIAN").

## ***SSNA103 - Chock of the parameters of the model of Weibull***

### ***Summary:***

*This test validates order RECA\_WEIBULL allowing the identification of the parameters  $m$  and the model of*

*U*

*Weibull.*

*The identification is carried out using a data base made up of 45 tests, all carried out on cylindrical test-tubes smooth at three different temperatures, -150°C, -100°C and 50°C. This base of data is obtained by random pulling of a sample representative of the statistical law of Weibull correspondent with values of  $m$  and  $U$  arbitrarily fixed.*

## ***2***

### ***Reference solution***

## ***2.1***

### ***Method of calculation***

*No calculation is necessary to obtain the reference solution. The values  $m$  and  $(M$  and  $U$   $SIGM\_REFE$  in option  $WEIBULL$  of  $DEFI\_MATERIAU$ ) which one seeks to identify with  $Code\_Aster$  are known and make it possible to generate the base of the experimental data. Thus, them elongations with rupture are in the following way given:*

*For each couple  $m$  and  $U$  associated with a temperature with test, a sample of 15 values of forced of Weibull to the rupture were determined by random pulling taking into account the law following statistics:*

$m$

$P$

$($   
 $) = 1 - \exp-$   
 $W$

$F$

$W$

$U$

*The constraint of Weibull is defined by:*

$m$   $V$   
 $= m (I$   
 $I$

$W$

$I)$

$V$

$I$

$0$

*The summation relates to volumes of matter  $V$  plasticized,  $I$  indicating the principal constraint  $I$   $I$*

*maximum in each one of these volumes (volume  $V0$  ( $VOLU\_REFE$  in option  $WEIBULL$  of  $DEFI\_MATERIAU$ ) is equal to  $(50 \mu m)^3$ ).*

*In the case of a request in simple traction with the assumption of the small deformations,*

*forced of Weibull, W, according to the elongation with the rupture (l-l<sub>0</sub>) /l<sub>0</sub> is expressed, according to:*

$$\frac{L - L_0}{L_0} = \frac{E}{E_0} \left( \frac{V}{V_0} \right)^m$$

$$\frac{W}{W_0} = \frac{T}{T_0} + \frac{Y}{Y_0} \left( \frac{l_0}{l} \right)^m$$

0

*One thus deduces from this expression and preceding random pulling the values of lengthenings with rupture deferred in the table of [§1.3].*

## *2.2 Sizes and results of reference*

*The reference variables of m and used to create the bases of experimental tests are the following ones:*

*Temperature [°C]*

- 50
- 100
- 150
- m
- 24 24
- 24
- U [MPa]
- 2800 2700
- 2600

## **2.3**

### ***Uncertainties on the solution***

***Uncertainty on the solution cannot be given in a precise way. It can be rather high. Indeed, the values of reference can be found only if populations are considered experimental made up of an infinite number of samples.***

***SSNA112 axisymmetric Test of wrenching  
(Borderie & Pijaudier- Pooch) for the study of  
steel-concrete connection: law JOINT\_BA***

***Summary:***

*In this case test of mechanics one modelled the test of wrenching carried out by Borderie & Pijaudier-Pooch [bib1] of which the goal was to study the influence of the state of stress in the matrix on the properties mechanics of the interface. The geometrical data and the characteristics materials result from their report/ratio, and the numerical results will be compared with the experimental results.*

*For axisymmetric modeling, one uses elements QUAD4 for the concrete and steel, in combination with elements joint for the interface (see Doc. [R3.06.09]). The concrete and steel are considered elastic so to test only nonthe linearity of the law of behavior of connection steel concrete, JOINT\_BA (see document [R7.01.21]). One carries out a monotonous calculation with the displacements imposed at the end of the bar of steel.*

## Reference solution

*It is about a numerical comparison - experimental. The work of Borderie & Pijaudier-Pooch [bib1] consisted in a trial run of wrenchings carried out on fibres and reinforcements for reinforced concrete. The object of these tests was to study the influence of the state of stress in the matrix on the mechanical properties of the interface.*

*Each specimen was a cube of 80x80x80 mm whose concrete paste was Grade C30/37 (gravel of 16 mm) with a resistance to the moment of the test (three days after the casting and with a treatment 4 hours thermics) of 14.5 MPa, a Young modulus of 15.500 MPa and a Poisson's ratio from 0,17. For the reinforcements, they used deformed bars 8 mms in diameter, with a length of steel-concrete contact of 45 mm, plus 10 mm free at the edge of the concrete, which allowed to eliminate the singularities in the field from the concrete stresses in the embedded surface of the cube. The test was carried out with controlled displacements ( $\dot{u} = 8.3 \times 10^{-3}$  mm/s) and four levels of containment: 0, 5, 10 and 15 MPa, constant during each experiment.*

### ***Summary of the results***

*With lower deviations than 5.0% compared to the experimental results obtained by Borderie & Pijaudier-pouch [bib1], one considers that the axisymmetric simulation of the test of wrenching is satisfactory. However, in order to test the stability of the law of behavior in combination with other laws (law MAZARS for the concrete, for example), it will be necessary to decrease the size of the steps of time by considering that the other laws are made normally for formulations into small deformations.*

*The reference solution is obtained by carrying out same calculation with the model of Rousselier in viscous version ( $COMP\_INCR = "ROUSS\_VISC"$ ,  $DEFORMATION = "PETIT\_REAC"$ ) of which them*

*parameters were selected in order to return the effect of negligible porosity.*

*One compares the contraction of the ligament, i.e. displacement following X of the P1 node like resulting effort ( $REAC\_NODA$ ) on face P8P9. One is interested in 3 values of  $U_d$  displacement: 0.05mm, 0.5mm and 1mm.*

**Summary of the results**

***One obtains a good agreement of the results between the 2 models with lower deviations than 1%.  
At the total level, one notes that to the maximum 4 iterations are necessary to obtain convergence.  
On the level of the integration of the law of behavior, less than 10 iterations are necessary for  
to obtain an accuracy of 10-9.***

### ***Appear 1.1-a: Diagram of the field and loading***

*The assumption of an axisymmetric solution is made what enables us to restrict our study has one rectangular field 2D. Dimensions of the field are as follows*

*:*

*RF = 0.5mm, R = 5.5mm, L = 10mm. The loading on the rigid reinforcement will be taken into account by applying displacement imposed I*

*U ez on all side I of the field 2D like one*

*null displacement on the side E to take into account the embedding of the cylinder. Finally one imposes a radial displacement no one on the faces lower and higher of the field in order to avoid a singularity dependent on a change of boundary condition at points A and A (see [Figure 1.1-a]). These conditions in extreme cases will lead to a anti-plane solution (independent of Z) what makes it possible to obtain more*

*simply an analytical solution.*

## **1.2 Parameters**

### **Material**

*Values of the Young modulus, the Poisson's ratio, the critical stress and the tenacity of material are taken in the following way:*

$$\begin{aligned} -1 \\ E &= 1.5 \text{ MPa}, \nu = 0, C = 1.1 \text{ Mpa}, C \\ G &= 0.9 \text{ N.mm} \end{aligned}$$

*(They are of course values “tests” which does not correspond to any material in particular.)*

### **Reference solution**

*The reference solution is an analytical solution draw from [bib3], it even inspired from a study unidimensional proposed in [bib1] and in a more general way being based on the approach energetics of the rupture suggested per G.A. Francfort and J.J. Marigo [bib2]. We will not return in the details of the calculation of this solution, we will present just the analytical value of the answer total of the structure: displacement imposed  $U$  according to the corresponding force  $F$ :*

( )

$F L$

$$U F =$$

$$+ \operatorname{sign}(F)$$

$$1$$

$$F$$

$$-$$

$$\dot{e}q$$

$$2-1$$

$$2 R \mu$$

$$F L$$

$$2 R$$

$$F L$$

where  $\mu$  indicates the coefficient of Lamé ( $\mu = E/2$  here), the density of energy of cracking (see documentation [R7.02.12]) and where  $L = RF \ln(R/RF)$  is a length structural feature decisive for the brutal or progressive evolution of decoherence.

### 3 Modeling With

#### 3.1 Characteristics of modeling

Simulation is carried out into axisymmetric. The elements with internal discontinuity allow to represent the crack along I. The latter have as a modeling `AXIS_ELDI` and one cohesive behavior `CZM_EXP`. The other elements of the grid are `QUAD4` with one elastic behavior `ELAS` in modeling `AXIS`.

#### 3.2 Characteristics of the grid

One carries out a grid structured in quadrangles of the field with 76 meshes in the height and 28 meshes in the radial direction. One lays out a layer of elements with discontinuity interns length of I using order `CREA_MAILLAGE` and key word `CREA_FISS` (see documentation [U4.23.02]). The orientation of the elements with discontinuity is carried out so that the direction normal is directed according to  $-\mathbf{er}$  (the tangential direction is thus according to  $-\mathbf{ez}$ ). The remainder of the field is divided into linear meshes `QUAD4` (see [Figure 3.2-a]).

### 3.4 Sizes tested and results

The tangential constraint  $T$  along the crack (i.e in the elements with discontinuity) corresponds to opposite of the force  $F$  divided by the surface of decoherence:  $2 R F L$ . Moreover while resting on form density of energy of surface defined in [R7.02.12] and according to [éq 2-1] one deduces following relation:

$$\begin{aligned} & ( ) \\ & L \\ & \\ & T \\ & = - \\ & + sign ( ) C \\ & G \\ & U \\ & \\ & T \\ & T \\ & ln \\ & T \\ & \mu \end{aligned}$$

**4*****Summary of the results***

*It is noted that the element with discontinuity allows a good prediction of decoherence, indeed this last develops in an identical way on all the height of the cylinder moreover the results*

*numerical are very close to the analytical solution. In addition modeling suggested allows to correctly reproduce the brutal or progressive evolution of cracking according to lengths characteristic  $L$  of the structure and  $C$   $G$   $C$  of the behavior. This last point is not highlighted here but the interested reader will be able to refer to [bib3] for more details.*

***SSNA116 - Triaxial compression test with the model of Hoek-Brown modified into axisymmetric***

***Summary***

***This test makes it possible to validate the elastoplastic law of behavior of Hoek-Brown modified in***

*mechanics of rocks. It is about a triaxial compression test for which calculations are carried out only on the solid part of the ground in pure mechanics. Two levels of containment are applied: 5 MPa and 12 MPa. The parameters end , rup and LMBO are taken equal (what returns to a constant voluminal plastic deformation): one can in this case calculate one analytical solution with the problem and thus to compare the results obtained with Code\_Aster with this solution of reference. For reasons of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test. modeling is axisymmetric.*

### 1.3 Conditions

*initial,  
with the limits and loading*

*The test breaks up into two phases:*

*1) Initially, one brings the sample in a homogeneous state 0*

0

0

= =. For

xx

yy

zz

*that, the corresponding confining pressure is imposed on the front faces ( $Z = 1$ ),  
side right-hand side ( $X = 1$ ) and higher ( $y = 1$ ), while displacements are taken null on  
the faces postones ( $U$*

*= 0), side left ( $U$*

*= 0) and the lower ( $U$*

*= 0 ).*

Z z=0

X x=0

y y=0

*2) Once the homogeneous state obtained, displacements are maintained blocked on the faces  
back, side left and lower and the confining pressure are always imposed on  
front faces and side right-hand side. A displacement is imposed on the higher face ( $U(T)$ )*

y

*in order to obtain a deformation equalizes to 25% starting from the beginning of the second phase,*

yy

*by constant increments of deformation*

= - 5

.

2nd - 4.

yy

2

*Reference solution*

2.1

*Calculation of the reference solution*

*One places here in the case of a triaxial compression test for which the constraints of containment are applied in directions  $X$  and  $Z$  and for which the direction of imposed deformation is the direction  $y$ . One supposes moreover that the parameter is independent of the parameter of work hardening, i.e. end*

*rup*

*LMBO*

*=*

*=: it is then possible to calculate an analytical solution with the problem.*

*The criterion of plasticity and flow are written:*

**V6.01.301 document**

**SSNA301 - Melts of pressurized thick tank**

**Summary:**

***This test consists in analyzing until the ruin, the spherotoric bottom of a thick tank subjected to a pressure***

***intern by taking of account the elastoplastic behavior of material and the nonlinear behavior of the structure.***

***Modeling is made with axisymmetric elements of type MEAXQU8.***

***One will test the taking into account here or not nongeometrical linearities and the use of one or two assumptions material.***

## ***Summary of the results***

*The results provided by Aster concerning modelings A and C are close to the reference (variation < 0.6%). Moreover, one finds well the same results for modelings A and C; what is normal because the lower part remains elastic.*

*For modeling B, variations of results between Code\_Aster and reference (the SAMCEF software) 3.3% reach and come owing to the fact that nonthe geometrical linearities are treated in manner different in Code\_Aster (by order "PETIT\_REAC") and in the SAMCEF software.*

***SSNA302 - Plate circular simply supported***  
***subjected to pressure***

***Summary:***

***This test consists in applying a transverse pressure to a circular, simply supported plate and composed of an elastic material. It is intended to study the taking into account of nonthe geometrical linearities particularly in the absence of initial curve when the transverse stiffness is only due to the effect of plate.***

*Modeling is made with voluminal elements of type HEXA20 and PENTA15 and elements surface of type QUAD8 and TRIA6 for the application of the pressure.*

*The reference is software the SAMCEF software. One has for information the results resulting from the theory of the hulls thin.*

*Order COMP\_ELAS with option "GREEN" is compared with COMP\_INCR with option "PETIT\_REAC".*

*2*

*Reference solution*

*2.1*

*Reference solution*

*The reference is software the SAMCEF software. , For information, in the paragraph [§2.2], they are presented*

*theoretical results related to an assumption of thin the hull type. Then, the results are presented obtained with the SAMCEF software according to whether one chooses an assumption of thick the hull type or type volume. It is the latter which is taken into account for the evaluation of Code\_Aster.*

*2.2*

*Analytical solution and results of reference*

*The following formula gives the arrow  $w_0$  to the center of the plate:*

W  
W3

LP R 4  
0

+ A  
0  
H

H = E H with A = 1.852 and B = 0.696

The constraints with mid thickness are worth:

2  
=  
w0  
rr  
R E r2 2

w0  
= T E r2

The constraints in lower skin are worth

W H  
, =  
0  
rr  
R E r2  
W H  
,  
0  
= T E r2

The coefficients are worth:

In the center of the plate:

=  
R  
T = 0.905  
=  
R

***T = 1.778***

***At the edge of the plate:***

***R = 0.610***

***T = 0.183***

***R = 0***

***T = 0.755***

***For a pressure of 222.72 MPa, the arrow w0 is worth 1.5 mm and one obtains the following constraints:***

***Position***

***rr (MPa)***

***(MPa)***

***rr `(MPa)***

## ***3 Modeling***

***With***

### ***3.1***

***Characteristics of modeling A***

***Face 1:***

***Fixing on X***

***Appear 3.1-A: Face 2: Fixing on y***

*Only one quarter of plate is modelled. One introduces conditions of symmetry on the two faces shown above.*

*Moreover one fixes according to X, y, Z all the nodes of the edge located at semi thickness.*

*In order to most accurately represent the assumptions of thin hull, constraints are introduced linear on the degrees of freedom of the nodes of the edge. Those  $C_i$  are written:*

*for two nodes I and J located on both sides of the average layer:*

$$u_i + u_j = 0$$

$$v_i + v_j = 0$$

*where U and v indicate displacements along axes X and Y.*

*The syntax used in the data file of Code\_Aster is as follows:*

*LIAISON\_DDL (Node: Nor Nj), DDL: ("DX", "DX"), COEF\_MULT: (1, 1), COEF\_IMPO: 0*

*One applies the pressure linearly by using 6 increments.*

Axial rigidity of the cable (produced Young modulus by the surface of the cross-section): 5 X 107N

#### **1.3**

### **Boundary conditions and loadings**

The points O, C and P2 are fixed.

The cable, fixed out of O, is pressed on two pulleys. First is attached at the lower end P1 of suspension fixed out of C. second is fixed at P2.

The cable is subjected to its weight and one gives him arrow by moving his right end of 10 m of R2 with R'2.

The position of the points Q1, R1 and Q2 is not imposed, but one must make so that with the course pose the P1 pulley remains on the length of cable Q1 R1.

### 3.4 Remarks

On the basis of a horizontal rectilinear cable in weightlessness, one applies gravity while increasing length of the cable between O and P2 of 10m by the displacement of R2 in R'2 ( $R2 R'2 = 10 \text{ m}$ ). Like not tended right cables do not have rigidity for the transverse loads, one cannot apply from the start the loading case preceding bus one would lead to a singular system of equations. Calculation is thus done in 2 stages:

- one puts the cables in prevoltage by applying a tension to the cable itself in R2 and to the suspension in P1 (one suggests taking tensions of 10.000 NR);
- one makes a continuation on the preceding situation of balance by applying gravity and it displacement R2 R'2. The load of gravity will be declared of type "SUIV", because of elements MEPOULI of which the 2 parts are variable length.

## **Handbook of Validation**

### **V6.02 booklet: Nonlinear statics of the linear structures**

#### **Document: V6.02.101**

#### **SSNL101 - Non-linear behavior of an element of conductor arrangement**

##### **Summary:**

One considers in this test, 1 discrete element with 2 nodes subjected to a transverse effort in static analysis not linear.

The element has a behavior governed by a nonlinear relation expressed in effort and displacement one-way in transverse and local direction  $Y$ .

The interest of the test is to simulate in an exhaustive way the ways of possible loading, in load and discharge, in each field of the relation of behavior: rubber band, plastic and ultimate.

The reduced dimension of the problem with 1 unknown factor (the transverse displacement of the end) makes it possible to have

as solution the result d'1 algebraical expression found exactly by Aster.

#### **Problem of reference**

##### **1.1 Geometry**

1 discrete element of null size to 2 nodes.

Locate local = total reference mark.

1 matrix of rigidity “K\_TR\_D\_L” affected by defect:

1.6 N/m in translation, 1.9 N/m in rotation.

The characteristics of rigidity according to the local direction  $y$  (here with the total axis  $Y$  equalizes) are modified by

a relation of behavior of the type “ARMS” in effort-displacement introduced by a material characteristic.

## 1.2

### Material properties

Dependent on an incremental behavior “ARMS” with 5 parameters: *of* (key word “DLE”) = 0.048 m, *dl* (“DLP”) = 0.7 m, *Kel* (“KYE”) = 1.67 E4 N/m, *Kpl* (“KYP”) = 2.9 E3 N/m, *KG* (“KYG”) = 1 E6 N/m.

“*of*” displacement elastic range limits,

“*dl*” displacement limits plastic range,

“*Kel*” slope of the elastic range,

“*K pl*” slope of the plastic range,

“*KG*” ultimate slope,

Behavior of an arm of armament in longitudinal request

*F*

*KG*

*Fm*

## **4.2 Notice**

***The reference solution is the numerical solution of a problem to an unknown factor determined by Code\_Aster.***

**5**

***Summary of the results***

***The interest of the test is to represent the exhaustiveness of the possible ways of loadings with multiple factors of change of incline: load-discharge, transition from mechanism.***

***On the other hand, the dimension of the problem makes it possible to have only one unknown factor (the internal variable current), solution of the inversion of the curve of the law of behavior: direct solution for 1st mechanism and incremental for the second.***

***The reduction of the problem makes it possible (if one converges) to trust Aster like “slide rule” and to regard the result as a numerical solution “exact”.***

1.00003

0%

##### **4.2 Remarks**

For this problem, convergence is exceptionally fast: 2 iterations. For the problems of great rotations, static balance is in general reached in an iteration count of about 10.

### **4.3 Parameters of execution**

Version: NEW3

Machine: CRAY C90

Obstruction memory:

8 MW

Time CPU To use:

4,4 seconds

**5**

### **Summary of the results**

The deformation of the modelled beam is a CLOSED PENTAGON. But nodes, in situation deformation, are apart from the circle of reference because the elements of beam MECA\_POU\_D\_T\_GD preserve their length but remain right instead of becoming deformed in arcs of ring.

**SSNL105 - Tally stayed**

**Summary:**

Test of mechanics of the structures in static nonlinear elasticity.

The framework is made of pin jointed struts. The stays consist of two cables. Only one modeling is built.

This test makes it possible to check the behavior in traction and compression of the elements of cable (traction possible,

null compression) and the elastic behavior of the bars.

***V6.02.106 document***

***SSNL106 - Elastoplastic beam in traction  
and pure inflection***

## **Summary:**

***This test validates elastoplasticity in a right beam in traction and inflection, for a behavior elastoplastic perfect or with linear work hardening.***

.

***Analyze static***

.

***Elastoplastic behavior of beam: VMIS\_POUTRE or of PIPE***

.

***3 sections: rectangular, circular full, hollow circular***

.

***3 types of work hardening: no one, linear (ECRO\_LINE), nonlinear (ECRO\_FLEJOU)***

***8 modelings make it possible to test elements POU\_D\_TG, POU\_D\_E, POU\_D\_T, PIPE (3 and 4 nodes)***

***COQUE\_3D, POU\_D\_EM and POU\_D\_T\_GM.***

***The test makes it possible to validate the operation of the integration of these laws of behavior and of the algorithm of resolution until complete plasticization of the beam.***

***One also tests plasticization in alternating bending. Moreover, the two methods of resolution are tested for modelings of beams with total plasticity (POU\_D\_TG, POU\_D\_E, POU\_D\_T): implicit integration or by Runge-Kutta of order 4.***

***The ninth modeling makes it possible to test the operation of DYNA\_NON\_LINE on a calculation quasi-static of traction of a beam modelled in POU\_D\_TG.***

 &U \\
 &y \\
 &E \\
 &front \\
 &\mu \\
 &EC. = \\
 &= \\
 &= \\
 &R \\
 &ER
 \end{aligned}$$

In discharge, after having reached the limiting load charges some, one obtains a limiting load of sign opposite.

**Handbook of Validation**  
**V6.02 booklet: Nonlinear statics of the linear structures**  
**HT-66/04/005/A**

---

**Code\_Aster** ®

**Version**

**7.3**

**Titrate:**

**SSNL106 - Elastoplastic beam in traction and pure inflection**

**Date:**

**25/10/04**

**Author (S):**

**J.M. PROIX, J.L. FLEJOU**

**Key: V6.02.106-C Page: 5/16**

**for the tubular section:**

**(assumption of beam of Navier-Bernoulli)**

**The limiting load ( $H = 0$ ) is worth:**

$$\frac{M}{4} = M_e$$

**The complete solution for a thin tube is [bib1]:**

$$M(\mu) = \frac{M_e}{2} \left( 1 - \mu^2 \right) + \frac{M_e}{2} \arcsin \mu + \frac{M_e}{2} \mu \left( 1 - \mu^2 \right)$$

$$E \frac{H}{T}$$

*and*  
*E* =

*E H*  
*U*  
 -

*If = 1, one finds according to while solving:*

(  
*p*  
 -  
*p*  
*p*  
 y)  
  
*l* +  
 = *E*.

*U*

*What leads to the equation of the 2nd degree in:*

*2 - (E (+ U) + U) + E (+*  
*y U*  
*U) = 0*

*Then:*  
 = (*E* (+  
*p*  
*U) - U) 2 + 4th. E. 2u*

*and*  
*l*  
 = (*E* (+ *U*) + ±  
*U*  
 )  
 2

*The solution corresponding to the beginning of plasticization (growing starting from y) is that corresponding to the sign -.*

Thus the normal effort in the beam is:

2

S (  
U B)

(  
U B)

2  
NR =  
E  
+

E  
  
+ 4th E p

## **19 Modeling**

### **I**

#### **19.1 Characteristics of modeling**

*2 elements POU\_D\_TG by type of section. There are thus 2 groups of elements comprising each one 2 elements.*

**Group GR1:**

*rectangular section*

**GC1:**

*circular section*

**Simple traction:**

*on GR1 (ECRO\_FLEJOU) and GC1 (ECRO\_LINE)*

**Pure inflection:**

*on GR1 and GC1 without work hardening*

#### **19.2 Characteristics of the grid**

*2 X 2 elements POU\_D\_TG*

#### **19.3 Functionalities**

*tested*

*The characteristic of modeling I is to test the operation of DYNA\_NON\_LINE in calculation of quasi-static traction of a beam modelled in POU\_D\_TG. This type of modeling has for characteristic to reveal null pivots on the lines of the matrix of mass corresponding with the degrees of freedom of warping. In this case, the initialization of the diagram of NEWMARK fact more by inversion of the matrix of mass, which is singular, but by zero setting of acceleration initial.*

## **20.2 Observations**

*It is noticed that the results in traction resulting from DYNA\_NON\_LINE are identical to those given by STAT\_NON\_LINE.*

*An alarm informs the user who the matrix of mass is singular, which should attract sound caution.*

*Indeed for the majority of the finite elements the matrix of mass is definite positive. A message invites it*

*thus to check the assignments of its model. In the framework of this modeling, the presence of degrees of freedom of warping naturally involves the singularity of the matrix of mass.*

**Key: V6.02.106-C Page: 15/16**

## **21 Summary of the results**

*The results obtained for a traction correspond exactly to the analytical solution. On the other hand in inflection, the difference reaches 0.5%. This is due to the criterion of plasticity chosen, whose form does not allow*

*not to find the analytical solution exactly. It is necessary to adjust as well as possible parameters AY, BY, AZ,*

**BZ.**

*With regard to modelings pipe and hull, the conclusions are the same ones, but this time the difference with the analytical solution comes from this solution which is valid for a beam of very mean tubular section, without effect of ovalization. This ovalization is blocked at the ends, it who allows to obtain a solution with less than 0.4% of the analytical solution.*

*Two modelings in multifibre beams provide a solution to less than 0.02% of analytical solution, for a very weak time calculation, compared to modeling pipe and hull, but without it being necessary to adjust parameters as for modelings of beam with total plasticity. The only approximation comes from the grid of the section.*

***SSNL107 - Plate embedded subjected to an inflection  
by beams in contact with the free edge***

## **Summary:**

***This test validates the unilateral contact between elements of beam POU\_D\_E (right beam of Euler) and elements of hull DKQ.***

***The principal characteristics are:***

- linear behavior,***
- analyzes elastic,***
- unilateral contact,***
- 2 modelings: elements POU\_D\_E and DKQ by using CONTACT in AFFE\_CHAR\_MECA and in AFFE\_CHAR\_MECA\_F.***

***The reference solution is analytical and the results obtained are of good quality.***

***=  $K U < \mu R = \mu R$***

***, U***

***T***

***E***

***T***

***N***

***No***

***T increases.***

***In this phase, RT is strictly lower than  $\mu RN$  and one thus does not have friction.***

*Limit  $T_1$  of this phase is defined by*

$$: R = K U = \mu R$$

*T*

*E*

*T*

*No i.e. for*

*0 0*

$$. 1 K G (T_1) = \mu R$$

*E*

*No.*

*One finds  $T_1 = 4$ .*

*Without work hardening:*

*2nd phase:  $R$*

$$= \mu R = \mu R$$

*,  $U$*

*T*

*N*

*No*

*T increases.*

*The tangential force reached the value of the threshold  $\mu R_{no}$  and one thus has slip. This phase is delimited by the moments  $T = 4$ . and  $T$*

*1*

*2 = 10. (moment when  $U T$  starts to decrease).*

*3rd phase:  $R$*

$$= K U < \mu R = \mu R$$

*,  $U$*

*T*

*E*

*T*

*N*

*No*

*T decreases.*

*In this phase,  $R T$  is lower than the value of the threshold  $\mu R_N$  and one is thus in a phase rubber band  $R = - K U + \mu R$*

*T*

*E*

*T*

*No.*

*The limits of this phase are  $T = 10$ . and  $T$*

*2*

*3 defined by:*

- 0 0

.  $1k G (T) + \mu R = - R$

$T$

$E$

No

No

> 10

3

3

## 5 *Summary of the results*

*The results are identical to the reference solution. This test validates the slip with friction of Coulomb introduced via a discrete element. This development allows in particular to model the connection between the grids and the fuel pins.*

*Handbook of Validation*

friction of Coulomb*

*Summary:*

*This two-dimensional problem makes it possible to test the law of behavior used to model the connection roasts*

*mix fuel pins of the fuel assemblies.*

*A reduction according to the time of the rigidity of the connection is taken into account in this test.*

*This test of nonlinear statics has only one modeling.*

### **Summary of the results**

The results coincide perfectly with the reference solution. This test thus validates the element of arises nonlinear allowing to model a contact with friction of Coulomb.

***SSNL111 - Three thermoelastoplastic bars***

***Perfect von Mises***

***Summary:***

*This quasi-static test enters within the framework of the validation of the relations of elastoplastic behavior.*

*Three perfect, parallel thermoelastoplastic bars, rotulées on a rigid support at an end and rotulées on a rigid bar with the other, undergo an external thermal loading.*

*This application, where all the fields are uniform in each bar makes it possible to validate 2 types of numerical modelings: massive finite elements (2D forced plane), plates and bars.*

## ***Isotropic work hardening***

*For a uniaxial traction, the criterion of plasticity is written:*

$$L - R(p) \leq 0$$

*where  $p$  is the cumulated plastic deformation*

$E$

$R(p)$

$R(p)$

$y$

$(\cdot) = \cdot$  and  $R =$

$T$

$E$  - And

*The criterion is written then:*

$- R(p)$

$- y$

$L$

$0$

*The tensor of the constraints is obtained by:*

$= \mathbf{A} \cdot ((\mathbf{U}) - p) - 3 (- \text{ref.})$

$K T T) \mathbf{Id}$

*One thus deduces the expression from it from:*

$L$

$= E (- T) - E p$

$\text{ref.}$

$L$

$(T =) 0$

*In our case,  $= 0$  thus:*

$= E - E p$

*with  $=$*

$L$

$L$

$L$

$- T$

*Thus:*

$\cdot$

*If  $L - R(p) < 0$ :*

$p=0$  and  $= E$

$L$

$L$

.

If  $L - R(p) = 0$ :

$y$

-

$p =$

$R$

$= - p$

$E$

$E$

$L$

$L$

***Application to the way of loading***

***Moment 1:***

$= E = 200\text{MPa}$  and  $R p$

$R p$

$y$

$() = + = 100\text{MPa}$  bus  $p=0$ .

*el*

*One has well -  $R(p) 0$ .*

*L*  
*The criterion is not crossed, the evolution is elastic: = 100 MPa and NR = 100kN*  
*L*

**Moment 2:**  
*The criterion is reached:*  
*11*

*E*  
*2*  
*=*  
*(*  
*10*  
*R*  
*+ y =*  
*2 0*  
*. 2.109 × 35*  
*. -*  
*10 3 + 2.108 = 205MPa*  
*L*  
*L*  
*)*  
*11*  
*9 (*  
*)*  
*E + R*  
*2 10 + 2 02*  
*. 10*  
  
*NR = 102 5*  
*. kN*  
*and p =*  
*-*  
*2.475 10 3*  
*.*

**Moment 3:**  
*One discharges elastically:*  
*= - p*  
*E*  
*E*  
*= 11*  
*-3 -*

$$\begin{aligned}
 &- \\
 &2\ 10\ 15\ 10 \\
 &2.475\ 10\ 3 \\
 &(\cdot \\
 &\cdot \\
 &)= -195MPa \\
 &L \\
 &L \\
 &NR = -97. \ K \\
 &5\ NR
 \end{aligned}$$

**Moment 4:**

One plasticizes again:

The criterion is written: -  $RP - y = 0$  with  $p = p + p$  where  $p$

$$\begin{aligned}
 &-3 \\
 &= 2\ 475 \\
 &\cdot \\
 &10 \\
 &1 \\
 &2 \\
 &1
 \end{aligned}$$

One thus obtains:

$$\begin{aligned}
 &y \\
 &- \\
 &p = \\
 &- p \\
 &2 \\
 &R \\
 &1 \\
 &= - E\ p \\
 &= - E\ (p - p \\
 &1 \\
 &2\ ) \\
 &R \\
 &E\ y \\
 &= \\
 &2^{nd}\ p \\
 &= -207\ 9
 \end{aligned}$$

. MPa

$R + E$   
1

-  
-

R

And thus  $NR = -103$

K  
95

.  
NR

### **Moment 5:**

One discharges elastically:

$= - p$

E

E

$= 11 - 3 -$

-

$2 \cdot 10^2 \cdot 10$

$10395 \cdot 10^3$

(

.

) =  $192 \cdot 1$

. MPa

L

L

$NR = 96 \cdot K$

05 NR

### **Moments 6 and 7:**

The reasoning is identical

One finds:

NR

=

.

10587kN

(inst.6)

NR  
= - .  
44  
K  
13 NR

***1***

***Problem of reference***

***1.1 Geometry***

***A cable length  $2l_0$  at rest, in direction  $X$ , is subjected its actual weight (gravity in direction -  $Z$ ). It is embedded with the ends  $O$  and  $B$ , themselves distant of  $2L$ .***

***Z***  
***2L***  
***O***  
***X***  
***O***  
***C***  
***2l0***  
***B***

***Initially,  $2l0 = 2L=325m$***

***The surface of the section of the cable is worth:  $2.2783E-04\text{ m}^2$***

***1.2***

***Material properties***

***$E = 5.70\text{ E}+10\text{ Pa}$***   
 ***$= 0.3$  (modeling *B* only)***  
***ALPHA:  $2.3\text{ E}-5\text{ K1}$***   
***RHO:  $2.844230\text{E}+03\text{ kg/m}^3$***

***1.3***

***Boundary conditions and loadings***

***Embedding out of *O* and *B****

***Gravity:  $(9.81, 0.0, 0.0, - 1.0)$***

***The temperature in the cable varies according to time:***

***Moment: 0.  $T=0$  temperature.  $^{\circ}\text{C}$***

***Moment: 1.  $\text{Température } T=39.26\text{ }^{\circ}\text{C}$***

***(The temperature of reference is worth:  $0.^{\circ}\text{C}$ )***

***One thus treats:***

***at moment 0, a cable subjected to its only actual weight***

*at moment 1, a heavy cable subjected to a thermal dilation.*

*Handbook of Validation*

***Summary of the results***

***The results show that one can obtain the solution of the problem of the heavy cable with good precision for the elements of cable (0.02%), and a precision acceptable for the elements POU\_D\_T\_GD (0.4%).***

***Indeed, this mechanical problem is difficult for the algorithm of resolution, because the solution cannot to be obtained that with the assumption of great displacements. Convergence can be obtained only with the geometrical matrix of rigidity.***

***SSNL117 - Bend in inflection in elastoplasticity***

***Summary:***

***This test validates the modeling of the phenomena of ovalization in pipings in the field elastoplastic with the elements PIPE: an elbow, prolonged by right pipes is subjected to an inflection in its plan. Piping is thick (of size similar to the elbows of the primary education circuits). reference solution is numerical: it is obtained with Code\_Aster using a grid 3D of the elbow.***

***Two modelings make it possible to validate the elements PIPE (with right and bent elements with 3 nodes for modeling A and of the right and bent elements with 4 nodes for modeling B) in elastoplasticity.***

***In modeling B, a term of “total” rotation, developed by EDF, ECA and FRAMATOME [bib2], for pipings under seism, is introduced via a Python macro-order.***

## ***Summary of the results***

*The reference solution not being analytical, but numerical (obtained by a modeling 3D), the noted variations (from 1% to 3%) can be regarded as reasonable. To obtain one better correspondence of the 3D solutions and PIPE, it would be appropriate to model the right parts over a bigger length, and to adopt a finer grid for each modeling. This was not made within the framework of this test, to keep reasonable execution times.*

### ***SSNL118 - Bar subjected to a field speed of wind***

#### ***Summary:***

***This test relates to the validation of the application of the loadings of wind on the linear elements. loading is described by fields speeds of wind.***

***This problem makes it possible to test:***

- ***linear finite elements [bars, cables, beams (except the curved beams)] with loadings follower of nature “wind”,***
- ***loadings representing speeds of wind:***
  - ***reading of the data of the fields of wind,***
  - ***projection of the fields of wind attached to the group of dots on the grid deformed of structure,***
  - ***calculation relative speed,***
- ***the taking into account of the function giving the force distributed according to the relative speed of structure,***
- ***the reactualization of the geometry to take account of great displacements and large rotations.***

*Effort due to the wind*

· *Vitesse of the wind in a point M bars*  
 $V_{vx}$

$$V_r = V_{vy}$$

with  $V_{vx}$ ,  $V_{vy}$ : speed of the wind following the axis “X” and centers it “y”.  
 $0$

· *Vitesse relating perpendicular to the bar to the point M:*  
 $\sin (q_0 + Q). (V_{vy}$   
 $-$   
 $\cdot \cos (q_0 + Q) + V_{vx}.\sin (q_0 + Q))$

$$\begin{aligned}
 &V_p = \cos (q_0 + Q). V_{vy} \\
 & ( \\
 & \cdot \cos (q_0 + Q) - V_{vx}.\sin (q_0 + Q))
 \end{aligned}$$

$0$

· *Force due to the wind in a point M*  
 $V_p$   
 $F_{vent} (M) = F_{cx} (M).$   
*in our case one chooses  $F_{cx}$*   
 $//V$   
 $(M) = //V_p//$   
 $p//$

one thus obtains  $F_{vent}(M) = V_p$   
 · Résultante from the force due to the wind on the bar  
 $L \cdot \sin(q_0 + Q) \cdot (V$   
 $- v_y \cdot \cos(q_0 + Q) + V_{vx} \cdot \sin(q_0 + Q))$

$F_{vent} = L \cdot \cos(q_0 + Q) \cdot V$   
 $(v_y \cdot \cos(q_0 + Q) - V_{vx} \cdot \sin(q_0 + Q))$

0

Equilibrium equation:  $F + B_{fr} + F_{vent} = 0$

## 2.2

### Sizes and results of reference

Displacements of the points A1 and B1 at the moments: 1. S, 1.05 S and 2. S. These moments correspond respectively at speeds of wind of 10, 15 and 20m/s

The resolution of the 3 equilibrium equations, projection of " $F + B_{fr} + F_{vent} = 0$ ", is done by iterations.

3 unknown factors of the problem are the position of the centre of gravity of the bar G: (X, y) and variation of

*the angle: .*

*In Code\_Aster, the effect of the wind is taken into account by a force distributed along the element linear. The expression of the module of this force distributed is as follows:*

$$F_{cx}(v) = \frac{1}{2} \rho V^2 C_x(v) D$$

*2  
H*

*where  $F_{cx}(v)$ : is the module of the force distributed along the cable in N/m, depend on speed.*

*$\rho$ : is the density of the air in kg/m<sup>3</sup>.*

*V: is the relative speed of the cable in m/s.*

*$C_x(v)$ : is the coefficient of drag of the cable, depend on relative speed.*

*Dh: is the hydraulic diameter of the cable in Mr.*

*To obtain a simple analytical reference solution, the function  $F_{cx}(V_p)$  is taken equalizes with  $||V_p||$ . In the command file of Code\_Aster the function of  $F_{cxv}$  is thus defined in a following way*

```
:

FCXV=DEFI_FONCTION (
NOM_PARA=' VITE',
VALE= (
0.0 ,
0.0 ,
10.0 ,
10.0 ),
PROL_GAUCHE=' LINEAIRE',
PROL_DROITE=' LINEAIRE',
)
```

## **2.3**

### ***Uncertainties on the solution***

*None. The resolution of the equilibrium equation is done by iterations with a <1.0E-09 error.*

## ***Reference solution***

***The reference solution is a calculation carried out using the computer code EFICOS [bib1]. It is about one***

***calculation multi-layer (2D) with the same models for materials. The elements do not comprise that a point of Gauss according to their axis and the total resolution is made by an algorithm with matrix secant.***

***To have comparable results in terms of localization and terms of local results***

***(constraints and deformations at the point of Gauss nearest to the medium of the beam), calculation with***

***EFICOS (1 point by element) is carried out with 10 elements) by half span while calculation with ASTER (2 points per element) is realized with 8 elements by half span.***

***This difference in integration is the principal source of the differences noted in paragraph 4.***

### **3 Modeling**

#### **3.1**

##### ***Characteristics of modeling***

***Longitudinal grid of the beam:***

***It is composed of 17 nodes and 16 pairs of elements POU\_D\_EM (16 elements for the concrete and 16 for steel).***

***Cross section of the beam:***

***The concrete is modelled by a grid (AFFE\_SECT) composed of 2 X 20 quadrilaterals (40 fibres)***

***Steel is modelled by 4 specific fibres (AFFE\_FIBRE)***

***The concrete is modelled with the model of damage of Christian Borderie in version 1D (LABORD\_1D) [R7.01.07].***

***The parameters material used are as follows:***

***Y01 = 310 Pa***

***Y02 = 7000 Pa***

***A1 = 9,0.10-3 Pa1***

***A2 = 5,2.10-6 Pa1***

***B1 = 1,2***

***B2 = 2,0***

***1 = 106 Pa***

***2 = -40.106 Pa***

***F = -3,5.106 Pa***

## ***SSNL120 - Cyclic response of the law of behavior of the concrete (model of Borderie)***

### ***Summary:***

***In this example one tests the model of behavior of the concrete of Borderie [R7.01.07] in his version 1D using a multifibre element of beam [R3.08] under axial stress. The loading is composed of traction with loading and unloading followed by compression also with loading and unloading. It allows to test resistances in traction and compression, to highlight the phenomenon of refermeture of cracks and to test the anelastic deformations.***

## **1.2**

### **Material properties**

**Young modulus:  $E = 2.10^{10}$  Pa**  
**Resistance in traction:  $R_t = 4.10^6$  Pa**  
**Resistance in compression:  $R_c = 40.10^6$  Pa**

## **1.3**

### **Boundary conditions**

**Embedding in a:  $dx = Dy = dz = 0$  and  $X\text{-ray} = r_y = r_z = 0$ .**

## **1.4 Loadings**

**One decreases to grow and the axial deformation (via a displacement imposed out of B according to X) according to the following sequence:**

### **Moment Deformation**

**0 0,0**  
**1  $1,4.10^{-4}$**   
**2  $0,5.10^{-4}$**   
**3  $1,0.10^{-3}$**   
**4  $-4,0.10^{-3}$**   
**5  $-2,0.10^{-3}$**   
**6  $-5,0.10^{-3}$**   
**7 0,0**

## **2**

### **Reference solution**

**The reference solution is the uniaxial response of the model for the parameters selected materials. This solution was obtained using the code Eficos (code with multi-layer beams 2D [bib1]) in which this law was established.**

**4 Modeling**

**With**

**4.1**

**Characteristics of modeling A**

**Longitudinal grid of the beam:**

**We have 2 nodes and 1 element (POU\_D\_EM).**

**With**

**B**

**The concrete part of the cross section of the beam is with a grid (AFFE\_SECT) by 4 fibres:**

**Note:**

**The problem being 1D, only one fibre could seem sufficient, but that would lead to**

*to have null terms in the matrix of rigidity (the own inertia of fibres not being taken in account) and with an error at the time of the solution of the system of equations.*

*The concrete is modelled with the model of damage of Christian Borderie in version 1D (LABORD\_1D) [R7.01.07]. The parameters material used are as follows:*

*Y01 = 310 Pa*

*Y02 = 7000 Pa*

*A1 = 9,0.10<sup>-3</sup> Pa-1*

*A2 = 5,2.10<sup>-6</sup> Pa-1*

*B1 = 1,2*

*B2 = 2,0*

*1 = 106 Pa*

*2 = -40.106 Pa*

*F = -3,5.106 Pa*

 $X = 0$   
 $L$   
 $10 \text{ mm}$   
 $0$   
 $-$   
 $l =$

*The studied structure is a 15 mm length bar. The problem being purely 1D, its section is without influence.*

## ***1.2 Properties of material***

*The material obeys a law of fragile elastic behavior (ENDO\_FRAGILE) to gradient of damage (modeling \*\_GRAD\_VARI).*

$ELAS \text{ ECRO\_LINE}$   
 $NON\_LOCAL$   
 $E = 20.000 \text{ Mpa}$   
 $SY = 2 \text{ Mpa}$   
 $NAKED = 0$   
 $D\_SIGM\_EPSI = - 20.000 \text{ MPa}$   
 $LONG\_CARA = 5.099 \text{ mm}$

## ***1.3 Conditions of loading***

*One forces the left part of the bar (5 mm length) to remain rigid (blocking of the degrees of freedom of displacement). As for the right part of the bar, it is subjected to an axial deformation uniform 0, i.e. with an imposed displacement whose spatial distribution is linear. Only one*

*parameter thus controls the intensity of the loading: the level of imposed deformation 0. In the directions perpendicular to the axis of the bar, displacements are blocked: the problem is purely 1D. Moreover, as the Poisson's ratio is null, no constraint of fastening develops in these directions.*

*Handbook of Validation*

*:*

*V6.02.125-A Page:*

*3/10*

*2*

*Reference solution*

*In the case of the law of behavior to gradients of damage [R5.03.18], two equations with derivative partial must be solved: the equilibrium equation and the equation of behavior. To obtain an analytical solution proves generally delicate, even for unidimensional structures.*

*To validate nevertheless this model, one sticks to a simpler problem for which the equation of balance need does not have to be solved, i.e. the field of displacement is fixed everywhere. The equation of behavior is then controlled by the elastic deformation energy  $W$  known in all not space.*

*2.1*

*Characterization of the solution*

*More precisely, one considers a bar of which a part is obligation to remain without deformation while the other is subjected to a homogeneous deformation. One studies the boundary layer then of damage which develops with the interface of these two zones. The differential equation of behavior is as follows in the zones where the criterion is reached, i.e. where the damage evolves/moves:*

*2*

$$2$$

$$D$$

$$y$$

$$I+$$

$$W = K (D) - C$$

$$where$$

$$K (D) = W$$

$$éq$$

$$2.1-1$$

$$2$$

$$^x$$

$$I+ - D$$

*where*

*y*

*W, and C are parameters of material, to see again [R5.03.18] for the correspondence with the sizes provided in DEFI\_MATERIAU, while  $x^$  indicates the variable of space. One henceforth standardize the variables of the problem while introducing:*

$$W$$

$$y$$

$$2$$

$$E =$$

$$X = x^ (I+)$$

$$W$$

$$= I+ - éq$$

$$2.1-2$$

$$W y (I+)$$

$$has$$

$$D$$

$$2$$

$$C$$

*With the help of these changes of variables, the equation of behavior is written:*

$$2$$

$$1$$

$$D has$$

$$E (X) =$$

+ 2

*éq 2.1-3*

2

2

*has**dx*

*There one recognizes an equation of motion in a gravitational field under an imposed force. It admits an integral first in each of the two zones of the bar (subscripted by I):*

*da* 2

1

*- - E has = C**I**I**I*

{,

0 }

1

*e0 = 0 e1 = E**éq**2.1-4**dx**has*

*To these two constants of integration  $C_i$  come to be added two other constants resulting from the integration of [éq 2.1-4]. These four constants are fixed by the two conditions of edge and them conditions of jump to the interface:*

*da**da**da**da**(L) =**(L) = 0*

+

-  
+  
-  
0  
1

$+ has (0)$   
 $has (0)$

*Thus, it appears that the profile of damage is completely controlled by its value into 0, i.e., taking into account the condition of continuity [  q 2.1-5], by what occurs in the zone charged.*

### 2.3 *Resolution of the problem in the zone charged*

*In the zone with null deformation ( $I = 1$ ), the integral first [  q 2.1-4] also seems a differential equation with separable variable. Taking into account [  q 2.1-6] and definition of  $I$  has,*  
*its integration leads initially to the following implicit equation (with the help of change of variable  $U = has - I$  has):*

*has (X) - a1*

*1 2*

*a1 (a1 + U)*

*X = L1 -*

*éq*

*2.3-1*

*E has u2*

*2*

*1*

*+ (ea1 -)*

*1 U*

*0*

*Again, it is about a clean integral, except in the case*

*2*

*E has*

*1*

*1 =, i.e.*

*the damage corresponding to the request E in a homogeneous problem. That means that the extreme damage 1*

*A is all the more close to the homogeneous solution the bar is*

*long: the boundary layer in the zone charged is not limited and asymptotically extends towards homogeneous answer.*

*Handbook of Validation*

*:*

*06/10/03*

*Author (S):*

*E. Key LORENTZ*

*:*

*V6.02.125-A Page:*

**6/10**

*By expressing the equation [  q 2.3-1] in  $X = 0$ , one obtain an equation making it possible to determine*

*has in  
function of  $A$  ()*

*0 :  
has (0) -  $a_1$*

*$a_1$  ( $a_1 + U$ )*

*$L_1 =$*

*  q  
2.3-2  
 $E$  has  $u_2$*

*2  
1  
+ ( $ea_1 -$ )*

*$1 U$   
0*

*However, to simplify the analytical resolution of this problem, it is supposed henceforth that the bar is sufficiently long, so that an approximate solution of [  q 2.3-2] is given by:*

*2  
1 2  
 $E$  1  
has  
= 1  
-*

*1  
=  $E$  has*

*  q  
2.3-3*

*As for the profile of damage in the charged zone, it is him also completely parameterized by  
has ()*

*0, since while combining [  q 2.3-1], [  q 2.3-2] and [  q 2.3-3] one obtains:*

*has (0)*

*has (0)*

*1 2*

*1*

*has*

*1*

*has*

*X =*

*D*

*= 2 1*

*has -*

*1*

*arg tanh has*

*éq*

*2.3-4*

*- 1*

*has*

*has (X)*

*has (X)*

*2.4*

*Determination of the damage to the interface*

*Let us reconsider the step of integration. Initially, we awaited four constants of integration:*

*C0, 1*

*C and two resulting from the integration of the integrals first [éq 2.1-4]. Then, to both constant C and C were substituted the two extreme values of damage has and*

*0*

*1*

*0*

*1*

*has, they*

*also unknown. By exploiting the boundary conditions of Neumann in [éq 2.1-6], one has implicitly given two complementary constants of integration not to express the profiles of damage that according to the only values a0 and 1*

*has, to see the equations [éq 2.2-1] and*

*[éq 2.3-1]. Finally, one substituted for the constants a0 and 1*

*with the value of the damage with  
the interface has ()*

*0, equalize on the left and on the right since the jump of A is null there. This substitution is  
operated by noticing that the damaged zone is of size finished in the discharged zone,  
contrary to the zone charged where we privileged an approached solution, simpler on  
analytical plan.*

*Consequently, there remains nothing any more but one constant of integration to be determined, the  
damage with  
the interface has ()*

*0 thanks to the last unutilised condition, the nullity of the jump of derived with the interface.  
Thus, by evaluating the two integrals first in  $X = 0$  and calculating their difference, one obtain:*

*1  
1  
E has ()  
0 = E has +  
-*

*éq  
2.4-1*

*1  
has  
has*

*1  
0  
By taking account of the expressions [éq 2.2-4] and [éq 2.3-3], one deduces the expression from it  
from  
the damage with the interface:*

*has (= 2  
)  
0  
-*

*1  
éq  
2.4-2*

*E  
E (1+)*

### **3 Modeling**

**With**

#### **3.1**

**Characteristics of modeling and the grid**

*It is about an axisymmetric modeling (AXIS\_GRAD\_VARI). Geometry corresponding is a rectangle, i.e. the bar is laid out of manner vertical and its section (without influence) are circular.*

*The grid consists of only one element according to the ray. According to the axis, smallest elements have a size of 0.1 mm along the interface and grow in progression*

*geometrical of reason 1.05 while moving away from the interface. Grid thus generated finally consists of 59 quadrangular elements with 8 nodes.*

## **4**

### **Results of modeling A**

#### **4.1**

##### **Sizes tested and results**

*One validates the modeling and the algorithm of integration of nonlocal laws by examining the level of damage (variable V1 intern) on the various levels of loading and the various places geometrical listed in [Table 2.6-1]. The results are joined together in the extract of the file of result below.*

**SSNL126 - Elastoplastic buckling of one  
right beam**

**Summary:**

***A slim right beam of circular section is subjected to a compressive force at an end, and is embedded at the other end. The behavior of material is elastoplastic, with an isotropic work hardening linear. During the rise in load, one calculates the critical loads of elastic buckling, then plastic.***

***Two modelings make it possible to test the criterion of buckling in elastoplasticity:***

***Voluminal modeling a: grid, small deformations and small displacements.***

***Modeling b: voluminal grid, small deformations and great displacements (GREEN).***

*The critical coefficient thus passes well by 0 between moments 6 and 7, and more precisely (curved cf following) in the neighbourhoods of moment 6.5, which corresponds well to the critical load in elasticity.*

*Coefficient criticizes Aster*

7  
***Summary of the results***

***The results as of modeling in small displacements is in conformity with the analytical reference (less than 2% of variation in plasticity). The results in great displacements cannot be compared with a reference solution, but the change of sign of the critical coefficient is conform to the awaited solution.***

***SSNL127 - Tensile test with the model***  
***CORR\_ACIER***

***Summary:***

***This test of nonlinear quasi-static mechanics makes it possible to validate the elastoplastic model endommageable CORR\_ACIER.***

***5 modelings make it possible to validate the behavior:***

- modelings A, B, C in 1D for the elements BARS, POU\_D\_EM, POU\_D\_TGM;***
- modeling D in 3D in the case of an axisymmetric test-tube (state of stresses and of homogeneous deformation) subjected to a simple tensile test; modeling 3D of the test-tube is realized with elements CU20;***
- modeling E in COQUE\_3D in the case of a plate subjected to a simple traction, with one net QUAD9.***

**Problem of reference**

**1.1 Geometry**

The geometry is selected voluntarily simple, to translate a state of stresses and of deformations homogeneous, as it is the case in uniaxial traction. In the case 1D and 3D, it acts here of a bar of diameter = 6 mm and length 100mm. In 3D, one nets only one quarter of bar. Traction is done with displacement imposed in 1D and 3D with the length of the test-tube. In 2

case COQUE\_3D, the plate is square on side 100mm, and thickness (so that the efforts are 4 identical to the case 1D).

### ***initial***

*Null constraints and deformations.*

## ***2***

### ***Reference solution***

#### ***2.1***

##### ***Method of calculation***

*The reference solution is consisted the results of the tensile tests carried out on bars corroded (the initial diameter is 6 mm). Following these tests, one notes the reduction in plastic deformation with rupture with increase in the degree of corrosion.*

**2.2*****Results of reference***

*Evolution of the plastic deformation with rupture of the bars corroded according to the degree of corrosion (the reduction of the diameter of bars or thickness of flat reinforcement compared to those not corroded) is presented on [Figure 2.2-a] and it [Figure 2.2-b].*

***SSNL129 Validation of laws VISC\_ISOT\_TRAC and  
VISC\_ISOT\_LINE on a tensile test***

***Summary:***

***This test consists in applying to an elementary volume a loading of traction. Three speeds of loading are modelled.***

***Modelings A, B and C make it possible to validate the law of behavior VISC\_ISOT\_TRAC (DEFORMATION=' SIMO\_MIEHE') in 3D, D\_PLAN and AXIS. For that, the results obtained are compared with the viscous law of Rousselier ROUSS\_VISC and degenerated DEFORMATION=' PETIT\_REAC' in order to it that the evolution of porosity is negligible. Modelings D, E and F make it possible to validate the integration of law VISC\_ISOT\_LINE (DEFORMATION=' SIMO\_MIEHE') in 3D, D\_PLAN and AXIS. For that, results obtained are compared with those given by law VISC\_ISOT\_TRAC for the same linear work hardening.***

**Problem of reference**

**1.1 Geometry**

*It is a question of testing the 2 viscoplastic laws of behavior VISC\_ISOT\_TRAC and VISC\_ISOT\_LINE on an Elementary Volume representative R of dimension 1mm, is a cube in 3D, the equivalent of one bar in plane deformations or of a cylinder into axisymmetric.*

***Boundary conditions and loadings***

*The element of volume is subjected to a homogeneous simple tensile test. It is thus blocked in X on the face [3,4] and in y on the face [1,3] (and possibly in direction Z) and subjected to one displacement U (T) in the direction y*

*However on the face [1, 2].*

*3 values of T are used 2000 S, 0.2 S and 0.002s, corresponding to speeds of deformations & of 10<sup>-3</sup> s<sup>-1</sup>, 10 s<sup>-1</sup> and 10<sup>3</sup> s<sup>-1</sup>.*

## **1.4 Conditions**

*initial*

*Null constraints and deformations with T = 0.*

2

## **Results of reference**

*For the model VISC\_ISOT\_TRAC which one tests in modelings A, B and C, the validation is done by comparison with the results obtained with the model ROUSS\_VISC whose parameters were selected in order to make negligible the evolution of porosity and thus to be reduced to the model viscoplastic “traditional”.*

*For model VISC\_ISOT\_LINE tested in modelings D, E and F, one compares the solution obtained with VISC\_ISOT\_TRAC for which one defined a linear work hardening (one only preserves the points ends of the curve used to validate this model).*

## *15 Summary of the results*

*With less than 1% of difference between model ROUSS\_VISC (degenerated) and the model VISC\_ISOT\_TRAC whatever the rate loading applied, one can admit that the addition viscous component in model VISC\_ISOT\_TRAC is correct.  
In addition very weak variations (lower than 0.02%) observed between the solutions obtained with VISC\_ISOT\_LINE and VISC\_ISOT\_TRAC for a linear work hardening, also allow to validate the establishment of model VISC\_ISOT\_LINE.  
In all the cases, less than 10 local iterations are necessary to reach convergence (precision 10<sup>-9</sup>).

## **Summary:**

***The objective is to test and validate one of the possibilities of the order AFFE\_CARA\_ELEM, option RIGI\_PARASOL, coupled with behavior DIS\_CHOC. This case test models a plate, considered as indeformable, posed on a carpet of springs.***

- The springs are modelled by DIS\_T (K\_T\_D\_L), that makes it possible to impose conditions on limits at the ends of the springs which are not related to the solid.***
- Behavior DIS\_CHOC allows a unilateral behavior of the springs, which leaves one possibility of separation of the plate with respect to the carpet of spring.***

### ***Summary of the results***

*The use of the discrete, affected elements on nodes or segments, with a material of the type DIS\_CONTACT and used with STAT\_NON\_LINE (behavior COMP\_INCR and relation DIS\_CHOC) allows to model a unilateral behavior of the springs.*

*The use of key word RIGI\_PARASOL of order AFFE\_CARA\_ELEM makes it possible to affect to springs of the stiffnesses proportional to the surface of the elements to which they are connected.*

*The behavior being unilateral, it is necessary that Code\_Aster makes several iterations for to find the position of balance. It is also possible to encounter problems of convergence dependent on a loss of precision, had with a bad conditioning of the matrix of stiffness during iterations. Stiffness of the springs being able to cancel itself from one iteration to another.*

#### *4.2 Remarks*

*The width for modeling COQUE\_C\_PLAN is imposed on 1 in Code\_Aster. In consequence, we multiplied by 1/b the loading to take account of the real width of beam.*

*In this analysis one uses to find the solution, a technique of resolution of the type imposed displacement ("DDL\_IMPO"). This method provides for each value of displacement imposed, a multiplying coefficient of the loading ("ETA\_PILOTAGE"). The value of the loading imposed in "AFFE\_CHAR\_MECA" is equal to the limiting pressure, consequently the value of reference of parameter "ETA\_PILOTAGE" is equal to 1.*

***In this analysis, one uses to find the solution, a technique of resolution of the type imposed displacement (“DDL\_IMPO”). This method provides for each value of displacement imposed, a multiplying coefficient of the loading (“ETA\_PILOTAGE”). The value of the loading imposed in “AFFE\_CHAR\_MECA” is equal to the limiting pressure, consequently the value of reference of parameter “ETA\_PILOTAGE” is equal to 1.***

***Calculations were stopped when the value of parameter ETA\_PILOTAGE was stabilized.***

***SSNL502 - Beam in buckling***

***Summary:***

***This test represents a calculation of stability of a beam comforts subjected to a compressive force to one end. It makes it possible to validate modelings finite elements COQUE\_3D with meshes TRIA7 and QUAD9 and modeling POU\_D\_T\_GD with meshes SEG2 in the non-linear quasi-static field into large displacements and in great rotations in the presence of instability (Buckling of Euler)***

***Displacements and the moments obtained are compared with an analytical reference solution.***

## **4.2 Remarks**

*The strategy of calculation used breaks up into two stages:*

· **Imposed Chargement:** *one imposes a disturbing load of 1/1000 of the critical load according to X to reveal the mode of buckling. This load is applied for  $P/P_{cr}=0.98$  and until  $P/P_{cr}=1.015$ .*

· **Imposed Déplacement:** beyond 1.01, the structure became very flexible, one imposes one increase in displacement DZ (option DDL\_IMPO in STAT\_NON\_LINE) for to determine the behavior postbuckling.

The use of the technique length of arc makes difficult the definition of the value of reference to to introduce into order TEST\_RESU, since these values cannot be imposed. For to define the values of reference, we sought the values of the closest possible DZ those listed in the table of [§2.2] and we deferred the values of the parameter of piloting and of DX which one was to obtain for the values of DZ in question.

## **9.2 Remarks**

*The strategy of calculation used breaks up into two stages:*

· **Imposed Chargement:** *one imposes a disturbing load of 1/1000 of the critical load according to X to reveal the mode of buckling. This load is applied for  $P/P_{cr}=0.98$  and until  $P/P_{cr}=1.015$ .*

- **Imposed Déplacement:** beyond 1.01, the structure became very flexible, one imposes one increase in displacement DZ (option DDL\_IMPO in STAT\_NON\_LINE) for to determine the behavior postbuckling.
- The results are in good adequacy with the reference solution from  $ETA\_PILOTAGE = 1.293$ . Before this value, the disturbing load (necessary to obtain buckling) degrades the solution, and the variations with the analytical solution are important (up to 80%). The corresponding values are the subject of tests of nonregression. But this variation is only related to the disturbing load, since by increasing the loading vertical, the good solution is found.

**Displacement DZ (m)**

**The critical load is well detected. The first two results corresponding to the loads  $P/P_{cr} = 1.015$  and  $1.063$  are correct, the maximum error is 3.5% for mesh TRIA7 and 2.2% for mesh QUAD9. Mesh QUAD9 gives better results.**

*If one continues calculations with the elements of hulls mesh QUAD9 continues to give better results. In the zone where displacements in DZ are most important, the error made on the load 9% reach on the quadrangles and go up to 30% on the triangles. Errors increase in this area because of the slopes of the curves. The solution beam of the code provides good results compared to the solution beam of reference.*

*The coefficient of correction of transverse shearing A\_CIS was put at 0.833, corresponding to thick hulls. The value (9000=106xH/L) which would have being taken into account does not allow to carry out calculations. It introduces a bad conditioning of the matrices of rigidity in increasing their disparities.*

## ***Reference solution***

**2.1**

### ***Method of calculation used for the reference solution***

***The reference solution was obtained numerically with ABAQUS 5.5. The grid used is constituted of elements ELBOW31 to 2 nodes with 6 modes of Fourier. The discretization used is following:***

***.  
Part AB: 24 elements,***

***.  
Part BC: 8 elements,***

***.  
Part CD: 12 elements.***

***Integration in the section is as follows:***

***.  
7 layers in the thickness,***

***.  
18 sectors in the circumferential direction.***

**2.2**

### ***Results of reference***

***Moment limits = 253.4 103 N.m for a rotation around Z of 0.22 rad to point D.***

**2.3**

### ***Uncertainties on the solution***

***< 2%***

## **4.2 Remarks**

*At the time of stage A, one gradually imposes the internal pressure and the effort due to the basic effect on the interval of time  $0 < t < 10$ . Then (stage B), one gradually imposes the bending moment on the interval of time  $10 < t < 20$ . To solve, one forces at the time of the stage B an increase in rotation DRZ of 0.4 rad to the solution obtained at the time of stage A.*

*The results obtained for modeling PIPE (SEG3 and SEG4) are rather far away from the solution of reference, (error of 20%). On the other hand, they are better for modeling TUYAU\_6M (error from 6%).*

*The deformation of the transverse section in the elbow is represented better by modeling TUYAU\_6M, adapted better to the modeling of the thin pipes. In this modeling, the displacements of the average surface of the pipe are broken up into Fourier series until order 6, instead of 3 for modeling PIPE. The modeling of reference uses a decomposition in Fourier series until order 6.*

**SSNP05 - Plate in traction-shearing:**

**viscoelasticity of Lemaître**

**Summary:**

*This test of nonlinear quasi-static mechanics consists in charging in traction-shearing a square plate. One thus validates the relation of nonlinear behavior of viscoelasticity of Lemaître (in 3D) for one nonradial loading. This test is drawn from guide VPCS of the SFM.*

*The plate is modelled by a voluminal element (HEXA8).*

*The results obtained by Code\_Aster are very close to the reference solution.*

***Summary:***

*This test quasi-static 2D forced plane, from guide VPCS, enters within the framework of the validation of relations of elastoplastic behavior. A plate, made up of a plastic material with work hardening linear kinematics, is subjected at the same time to a shearing and tractive effort.*

*The principal interest of this test lies in the nonradial character of the loading.*

### **SSNP15 - Plate in traction-shearing -**

### **Von Mises (isotropic work hardening)**

#### **Summary:**

This test quasi-static 2D forced plane, from guide VPCS, enters within the framework of the validation of relations of elastoplastic behavior. A plate, made up of a plastic material with work hardening isotropic linear, is subjected to a one and tractive effort of shearing.

The principal interest of this test lies in the nonradial character of the loading.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

In the plan (,  
3), the standard of von Mises results in the traditional distance, so that one  
can immediately predict the phases of load and discharge at the time of the way of loading,  
since they are respectively the phases where the standard grows or decrease:

Way of loading

Numerical values (; )

Phases of loading

3

With

A0 (123,8; 76,23)

O-A0 charges elastic

B0

To (151,2; 93,1)

A0-A charges plastic

A0

B0 (158,23; 89,12)

A-B0 discharges

B (257,2; 33,1)

B0-B charges plastic

B

#### 2.1.1 Step of resolution

Mechanically, it is about a test 0D controlled in constraint, the material being elastoplastic with criterion  
of von Mises and linear isotropic work hardening. For a loading controlled in constraint, one determines  
easily cumulated plastic deformation:

y

-

$F(, p)$

y

$eq$

$= - - R p 0$

$p =$

$eq$

in load

**éq 2.1.1-1**

R

The integration of the plastic deformation is of course more delicate. The equation of flow is written:

~

**p**

3

3

=

*eq*

*p*

**p**

~

=

2

2 *R*

in load

**éq 2.1.1-2**

*eq*

*eq*

Lastly, one will deduce the deformation via the relation from state:

*p*

*p*

= **p** + -

**E 1:**

*xx* = *xx* +

*and*

*xy* = *xy* +

**éq 2.1.1-3**

*E*

2  $\mu$

4/20

### **2.1.2 Treatment of the phase of radial loading**

Let us notice that in phase of radial loading, the law of flow [éq 2.1.2-1] is integrated directly:

~

**p**

$$= 3 p$$

2

#### **éq 2.1.2-1**

*eq*

The cumulated plastic deformation is then given by [éq 2.1.1-1], the plastic deformation by [éq 2.1.2-1] and total deflection by [éq 2.1.1-3]. With:

E

$$= 195.000 \text{ MPa}$$

$2\mu$

$$= 150.000 \text{ MPa}$$

R'

$$= 1.949, 29 \text{ Mpa}$$

One obtains:

p (A)

$$= 2, 0547 \cdot 10^2$$

pxx (A)

$$= 1, 4054 \cdot 10^2$$

xx (A)

$$= 1, 4830 \cdot 10^2$$

pxy (A)

$$= 1, 2981 \cdot 10^2$$

xy (A)

$$= 1, 3601 \cdot 10^2$$

### **2.1.3 Treatment of the phase of nonradial loading**

In the phase of loading nonradial B0 - B, one can parameterize the way of constraint by:

**0**

**0**

$$(Q) = \mathbf{B} + Q (\mathbf{B} - \mathbf{B})$$

with

$$0 \leq Q \leq 1$$

#### **éq 2.1.3-1**

fixed direction

As the way of loading remains confined in the traction-shearing plan (.), there will be interest with to represent the state of stress by a complex number:

= +

0

0

*I*

= and  $(Q) = B + Q B$

3

0

*eq*

(-) **éq 2.1.3-2**

fixed direction

The integration of the law of flow [éq 2.1.1-2], followed by an integration by part, makes it possible to express

plastic deformation:

1

1

2 *R* [

**p]** 1

1

*eq*

1

~

~

~

2

=

$dq = \ln ()$

*eq*

-

ln

*dq*

[  
]  
eq  
0  
2  
( )  
eq  
0 0  
0  
~ B  
- ~B

The adoption of the complex plan allows an easy calculation of the last integral:

1  
1  
1  
1  
1  
1  
(

$$\frac{\ln 2}{\ln 2} =$$
$$=$$
 $+$ 
$$=$$
$$\frac{e q}{\ln} \frac{d q}{d t} = - \frac{2 \operatorname{Re}}{\ln} \left( \frac{d q}{d t} \right) + \frac{2 \operatorname{Im}}{\ln} \left( \frac{d q}{d t} \right)$$

)  $dq = 2\text{Re}$

$B$   
 $B0$   
 $0$   
 $0$   
 $0$   
 $0$   
 $0$

-  
 $0$

Finally, the increment of plastic deformation on the B0 way - B is worth:

[  
 $B$   
 $\ln () -$   
 $p] B$   
 $3$   
 $B$   
 $3$   
 $\sim B$   
 $\sim B0$   
 $=$   
 $\ln () \sim$   
 $-$   
 $\text{Re}$

-  
**éq 2.1.3-4**  
 $0$

$eq$   
 $B$   
[  
]  
 $2 R$   
 $B0$   
 $2 R$   
 $B$   
 $B0$   
( )  
 $-$   
 $B0$

**2.2**

**Results of reference**

By calculating the plastic deformation cumulated by [éq 2.1.1-1], the plastic deformation by [éq 2.1.3-4] and the total deflection by [éq 2.1.1-3], one obtains:

p (B)

= 4, 2329 102

pxx (B)

= 3, 3946 102

xx (B)

= 3, 5265 102

One obtains:

pxy (B)

= 2, 0250 102

xy (B)

= 2, 0471 102

One will be interested in the values of the constraints, the deformations and the cumulated plastic deformation

at points A and B of the way of loading.

**SSNP101 - Plate in traction-shearing:**

**viscoelasticity of Lemaître (D\_PLAN)**

**Summary:**

This test of nonlinear quasi-static mechanics consists in charging in traction-shearing a square plate.

One thus validates the relation of nonlinear behavior of viscoelasticity of Lemaître in plane deformations for a nonradial loading.

The plate is modelled by an element 2D (QUAD4).

The results obtained by Code\_Aster are very close to the reference solution.

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

Calculation 3D Aster carried out with an element HEXA8 of which all the nodes have a displacement imposed no one

according to OZ. That makes it possible to constitute a reference for the case of the plane deformations (in the plan

(OX, OY)), where one does not have an analytical solution or results of other computer codes.

Operation in 3D of the non-linear viscoelasticity of Lemaître itself was validated with the assistance test SSNP05A.

**2.2**

**Results of reference**

$\nu$  and at the moment  $T = 30$  S,  $T = 3630$  S,  $T = 3660$  S and  $T = 3720$  S

$\epsilon_{xx}$

$\epsilon_{xy}$

**2.3**

**Uncertainty on the solution**

Uncertainty lower than 0.5%.

**Summary of the results**

***The comparison of the results resulting from the test Aster and those obtained numerically by another method by WATANABE are satisfactory (the maximum change is 3.4%).***

***It should be noted that the numerical results are sensitive to the grid in the vicinity of the notch and to form this notch. In particular if one models a crack the values obtained are false. In revenge, starting from a sufficient smoothness of the grid and ray of the notch, results numerical are stable. For more information, it is advised to consult the document [R7.02.07] and bibliographical references.***

***SSNP108 - Prestressed concrete element***  
***in compression***

## **Summary:**

*One considers an elementary structure made up of a square concrete plate crossed by a cable of prestressed whose neutral fibre is confused with the horizontal axis of symmetry of the plate. The vertical edge left of the plate is fixed. The cable is put in traction at its two ends in order to prestress toggle plate. The losses of tension along the cable are neglected.*

*The goal of this case-test is to validate, on a simple configuration, the method of calculation of the state of balance of a prestressed structure of concrete. The results are validated by comparison with an analytical solution.*

**Problem of reference**

### **1.1 Geometry**

*The concrete plate is square; the sides have even length  $L = H = 2 \text{ Mr}$ .*

*The thickness of the plate is worth  $E = 0,6 \text{ Mr}$ .*

*The cable crosses the plate horizontally, with middle height, without eccentricity in the thickness. The surface of the cross-section of the cable is worth  $Its = 1,5.104 \text{ m}^2$ .*

$y$   
 $2\text{ m}$   
With  
 $B$   
 $1\text{ m}$   
 $H = 2\text{ m}$   
 $0$   
 $X$   
 $L = 2\text{ m}$

## 1.2

### *Properties of materials*

*Material concrete constituting the plate:*

*Young modulus  $E_b = 3.10^{10}\text{ Pa}$*

*Material steel constituting the cable:*

*Young modulus  $E_a = 2.1.10^{11}\text{ Pa}$*

*The Poisson's ratio is taken equal to 0 for two materials; the direction thus is privileged of normal load application (direction  $X$ ).*

*The losses of tension being neglected, the various parameters being used for their estimate are fixed at 0.*

## 1.3

### *Boundary conditions and loadings*

*The lower top of the left edge of the plate, i.e. the node origin  $(0; 0)$ , are embedded: all DDLs of translation and rotation are blocked.*

*The higher top of this same left edge, i.e. the node  $(0; 2)$ , is supported bi-laterally: DDLs of translation blocked are  $DX$  and  $DZ$ .*

*One applies at the two ends of the cable (which are fixed on the concrete in A and B) a normal effort of*

*traction:  $(F_0; 0)$  with node A  $(0; 1)$  and  $(F_0; 0)$  with the node B  $(2; 1)$ , with  $F_0 = 2.10^5\text{ NR}$ .*

Y

NC001001

NC001005

X

NB001001

NB001002

*The concrete plate is represented by an element DKT, supported by a mesh quadrangle to 4 nodes.*

*A thickness  $E = 0,6 \text{ m}$  is affected for him, as well as a material concrete for which are defined them behaviors ELAS (Young modulus  $E_b = 3.10^{10} \text{ Pa}$ ) and BPEL\_BETON: parameters characteristics of this relation are fixed at 0 bus one neglects the losses of tension along the cable of prestressed.*

*Node NB001001 is embedded: DX, DY, DZ, DRX, DRY and DRZ are blocked. Node NB002001 is supported bilaterally: DX and DZ are blocked.*

*The cable is represented by 4 elements MECA\_BARRE, supported by 4 meshes segments with 2 nodes.*

*A surface of cross-section  $Its = 1,5.104 \text{ m}^2$  their is affected, as well as a material steel for which are defined behaviors ELAS (Young modulus  $Ea = 2,1.1011 \text{ Pa}$ ) and BPEL\_ACIER: parameters characteristics of this relation are fixed at 0 (neglected losses of tension), except for stress ultimate elastic for which a zero value is illicit ( $fprg = 1,77.109 \text{ Pa}$ ).*

*The F0 tension = 2.105 NR is applied to nodes NC001001 and NC001005. This value of tension is coherent with the values of section and yield stress, for a cable of prestressed of type strand.*

*The calculation of the state of balance of the unit plates and cable is carried out in only one step, it behavior being elastic.*

### **3.2** **Stages of calculation and functionalities tested**

*The principal stages of calculation correspond to the functionalities which one wishes to validate:*

- operator DEFI\_MATERIAU: definition of the relations of behavior BPEL\_BETON and BPEL\_ACIER, in the particular case where losses of tension along the cable of prestressed are neglected (default values of the parameters);*
- operator DEFI\_CABLE\_BP: determination of a constant profile of tension along the cable of prestressed, losses being neglected; calculation of the coefficients of the relations kinematics between the DDL of the nodes of the cable and the DDL of the nodes "close" to the concrete plate;*
- operator AFFE\_CHAR\_MECA: definition of a loading of the type RELA\_CINE\_BP;*
- operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance by holding account loading of the type RELA\_CINE\_BP.*

### ***4.2 Remarks***

***The computed values correspond indeed to those theoretically awaited. One obtains well a compactness for the concrete plate.***

***One observes an infinitesimal difference between horizontal displacement with node NC001005 belonging to the cable and horizontal displacement to nodes NB001002 and NB002002 of the plate of concrete. The recorded values should be identical, but the rounding errors appearing in the coefficients of the relations kinematics explain this infinitesimal difference.***

## **5 Modeling**

### **B**

#### **5.1**

##### **Characteristics of modeling**

*For this modeling, the nodes “cables” and “concrete” are confused.  
 The figure below gives a simplified representation of the grid.*

**N3**  
**N4**  
**Y**  
**N5**  
**N6**  
**X**  
**N1**  
**N2**

*The concrete plate is represented by 10 elements DKT, supported by 10 meshes QUAD4.*

*A thickness  $E = 0,6 \text{ m}$  is affected for him, as well as a material concrete for which are defined them behaviors ELAS (Young modulus  $E_b = 3.1010 \text{ Pa}$ ) and BPEL\_BETON: parameters characteristics of this relation are fixed at 0 bus one neglects the losses of tension along the cable of prestressed.*

*The nodes N1, N5 and N3 are embedded: DX, DY, DZ, DRX, DRY and DRZ are blocked.*

*The cable is represented by 5 elements MECA\_BARRE, supported by 5 meshes SEG2.*

*A surface of cross-section  $I_{ts} = 1,5.104 \text{ m}^2$  their is affected, as well as a material steel for which are defined behaviors ELAS (Young modulus  $E_a = 2,1.1011 \text{ Pa}$ ) and BPEL\_ACIER: parameters characteristics of this relation are fixed at 0 (neglected losses of tension), except for stress ultimate elastic for which a zero value is illicit ( $f_{prg} = 1,77.109 \text{ Pa}$ ).*

*The  $F_0$  tension =  $2.105 \text{ NR}$  is applied to the nodes N5 and N6. This value of tension is coherent with values of section and yield stress, for a cable of prestressed of strand type.*

*The calculation of the state of balance of the unit plates and cable is carried out in only one step, it behavior being elastic.*

## 5.2

### *Stages of calculation and functionalities tested*

*The principal stages of calculation correspond to the functionalities which one wishes to validate:*

.

*operator DEFI\_MATERIAU: definition of the relations of behavior BPEL\_BETON and BPEL\_ACIER, in the particular case where losses of tension along the cable of prestressed are neglected (default values of the parameters);*

.

*operator DEFI\_CABLE\_BP: determination of a constant profile of tension along the cable of prestressed, losses being neglected; calculation of the coefficients of the relations kinematics between the DDL of the nodes of the cable and the DDL of the nodes “close” to the concrete plate;*

.

*operator AFFE\_CHAR\_MECA: definition of a loading of the type RELA\_CINE\_BP;*

.

*operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance by holding account*

*loading of the type RELA\_CINE\_BP.*

***SSNP109 - Cable of excentré prestressing***  
***in a right concrete beam***

***Summary***

***One considers a right concrete beam, of rectangular section, crossed over his length by a cable of prestressed out of steel. The cable is right, parallel to average fibre of the beam, and passes to middle height of section of the beam, while being excentré compared to the average plan. The left section of the beam and the end left of the cable are fixed. The cable is put in traction at its right end, in order to prestress the beam in inflection-compression. The losses of tension along the cable are neglected.***

***The goal of this case-test is to validate the method of calculation of the state of balance of a structure of concrete prestressed by comparison with an analytical reference solution.***

### **Reference solution**

*The analytical solution of reference is determined by the theory of the beams.*

*A embed-free beam is considered. The geometrical characteristics are those defined in paragraph [§2.1]. The prestressed cable applies at the loose lead a normal effort of compression (- F; 0; 0) and a bending moment (0; eF; 0).*

*The solution of this problem is as follows:*

$xx \ 0$

$0$

$F$

$12ez$

**Tensor of the constraints:**  $= 0$

$0$

$0$  with  $xx = -$

$I +$

$2$

with the **boundary conditions**:  
*X* = 0 *y* = -  
*Z* = 0

in  
,  
,  
  
*y* = 0  
2

*When the effects Poisson are neglected ( $B = 0$ ), the solution in displacements is simplified as follows:*

$$U(X, y, Z) = -\frac{F}{E} \left( \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} \right)$$

$$B_{HP} = \frac{F}{E} \left( \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} \right)$$

$$W(X, y, Z) = \frac{F}{E} \left( \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} \right)$$

$$B_{HP} = \frac{F}{E} \left( \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} + \frac{1}{2} \frac{Z^2}{R^2} \right)$$

*The numerical values of reference are calculated using the analytical expressions above, by using for  $F$  the value with the overall balance of the normal effort in the cable:*

$$F = -F$$

$$B_{HP} + E S$$

*has has 1 +*

### **3 Modeling**

**With**

#### **3.1**

#### **Characteristics of modeling**

*The figure below gives a simplified representation of the grid of the beam.*

NB002001

NB002021

NC002001

NC002021

NB001001

NB001021

*The concrete beam is represented by 20 elements of the type DKT, supported per as many meshes quadrangles with 4 nodes.*

*A thickness  $p = 0,2$  m their is affected, as well as a material concrete for which are defined them behaviors ELAS (Young modulus  $E_b = 3.1010$  Pa) and BPEL\_BETON: parameters characteristics of this relation are fixed at 0 bus one neglects the losses of tension along the cable of prestressed.*

*DDL DX, DY, DZ and DRY of node NB001001 are blocked.*

*The cable is represented by 20 elements MECA\_BARRE, supported per as many meshes segments to 2 nodes. The ends left and right-hand side are respectively nodes NC001001 and NC001021.*

*A surface of cross-section  $I_{ts} = 1,5.104$  m<sup>2</sup> is assigned to the elements, as well as a material steel for which are defined behaviors ELAS (Young modulus  $E_a = 2,1.1011$  Pa) and BPEL\_ACIER:*

*parameters characteristic of this relation are fixed at 0 (neglected losses of tension), except stress ultimate elastic for which the value of  $f_{prg} = 1,77.109 \text{ Pa}$  is selected.*

*The DDL DX, DY, and DZ of node NC001001 are blocked.*

*The  $F_0$  tension = 2.105 NR is applied to node NC001021. This value of tension is coherent with values of section and yield stress, for a cable of prestressed of strand type.*

*The calculation of the state of balance of the beam unit and cable is carried out in only one step, its behavior being elastic. One carries out then two complementary calculations allowing of to determine the constraints in skins lower and higher ( $z = \pm p/2$ ) of the beam.*

### **3.2** **Stages of calculation and functionalities tested**

*The principal stages of calculation correspond to the functionalities which one wishes to validate:*

*.  
operator DEFI\_MATERIAU: definition of the relations of behavior BPEL\_BETON and BPEL\_ACIER, in the particular case where losses of tension along the cable of prestressed are neglected (default values of the parameters);*

*.  
operator DEFI\_CABLE\_BP: determination of a constant profile of tension along the cable of prestressed, losses being neglected; calculation of the coefficients of the relations kinematics between the DDL of the nodes of the cable and the DDL of the nodes "close" to the concrete beam, in the case of a excentré cable;*

*.  
operator AFFE\_CHAR\_MECA: definition of a loading of the type RELA\_CINE\_BP;*

*.  
operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance by holding account loading of the type RELA\_CINE\_BP.*

*One uses finally operator CALC\_ELEM option SIGM\_ELNO\_DEPL in order to calculate the constraints in lower skin then in higher skin of the beam.*

## **4.2 Remarks**

*The computed values correspond indeed to those theoretically awaited. One obtains well a state of inflection-compression for the concrete beam.*

## **5 Summary of the results**

*The results obtained are validated by comparison with an analytical solution of reference with one very good precision.*

*The particular functionalities tested are as follows:*

- .  
*operator DEFI\_MATERIAU: definition of the parameters characteristic of the materials steel and concrete allowing the calculation of the tension along the cable of prestressing, following the rules BPEL;*
- .  
*operator DEFI\_CABLE\_BP: calculation of the tension along the cable and the coefficients of relations kinematics between the DDL of the nodes of the cable and the DDL of the “close” nodes concrete beam;*
- .  
*operator AFFE\_CHAR\_MECA: definition of a loading of the type RELA\_CINE\_BP;*
- .  
*operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance by holding account loading of the type RELA\_CINE\_BP.*

***Summary:***

***This case test of mechanics is inspired by work of Willam [bib1] and was used in the benchmark EDF/Division R & D “Model three-dimensional of non-linear behaviors of the material concrete in cracking” [bib2] to evaluate the models of behavior dedicated to the concrete. It is characterized by a way of specific loading which creates a continuous rotation of the principal constraints. It is used here to test establishment of the model of Mazars in its local version (modeling 3D) and in its delocalized version (modeling 3D\_GRAD\_EPSI). The validation is carried out by comparison with the results obtained with code CASTEM 2000 with the LGCNSN (Central School of Nantes).***

## 2

### *Reference solution*

*It is about a comparison code-code. The reference used is the code Castem2000 (version 2001). The results were obtained by the LGCNSN (Central School of Nantes) with the same parameters materials and same discretization in time. Contrary to the calculation carried out with Code\_Aster, it Castem calculation was carried out in 2D under the assumption of plane constraints. The delocalized version of the model of Mazars was tested with a null length characteristic of way to check that one finds the same results as with the local version.*

## **Summary of the results**

*With very weak variations of about 0.05% to the maximum on the constraints in the phase non-linear and about 0.002% after complete damage on a test where loadings are not radial, one can consider that the establishment of the model of Mazars too well in local version that not-local, is faithful to the original model.*

perforated***

***Summary:***

***This test 2D in plane constraints quasi-static makes it possible to illustrate on a simple case the questions relative to elastoplastic modeling; it highlights the effects of structure, of stress concentration, of charge limit.***

***It is about a homogeneous rectangular plate, perforated in its center, consisted of an elastoplastic material with isotropic work hardening, whose initial state is nonconstrained, which is subjected to a traction at its ends.***

***One is interested in the elastoplastic solution in load. More precisely, the analytical methods allow to know a lower limit of the limiting load. By an elastoplastic calculation, one would like to find one limit higher.***

***The objective of the test is to show the possibilities of modeling and postprocessing with STAT\_NON\_LINE.***

***Modeling A corresponds to the first loading, and comprises the orders of examination***

*useful for the TP*

*Modeling B clarifies the procedure to carry out calculation until the limiting load, and for to model the discharge.*

### 3.4

#### ***Unfolding of the TP***

*This modeling (command files forma03a.com m) corresponds to a calculation in elastoplasticity for  $P$  going up to 5.4 MPa. It also contains (in the command file forma03a.com 1, to use in continuation) the orders necessary to the examination (traced graphic curves and postprocessing).*

##### ***3.4.1 Results of calculation***

*Before the throw calculation itself, it is necessary to define a base, on the machine of execution, which will contain all the results. One can launch provided calculation, to  $P = 5.4$  MPa in the goal post-to treat it. In card-indexing it result, one can observe how the maximum evolves/moves (on all elements) of component VMIS of field EQUI\_ELGA\_SIGM, as well as the maximum of internal variables.*

*One will be able to note on this level on the internal variables that:*

- *at moments 1 and 1.2, it does not have there plasticization,*
- *until moment 5.4, one is constantly in load.*

*and on the constraints:*

- *the maximum value of the criterion of Von Mises at the points of Gauss is always limited to 6 Mpa, what shows that the solution checks the law of behavior well.*

***Handbook of Validation***

***6.4***

***Titrate:***

***FORMA03 - Nonlinear TP2 static formation***

***Date:***

***16/07/03***

***Author (S):***

***Key J.M. PROIX***

***:***

**V6.03.114-B Page:****6/12****3.4.2 Use of the tools for examination**

*One will be able to use in continuation the command file forma03a.com 1, on the basis previously created.*

*It is necessary to define the files following results:*

- *a file of the type “cast” if one wants effector a graphic examination with GIBI,*
- *a file of the type “pos” if one wants effector a graphic examination using GMSH,*
- *of other files specific to the layouts of curves, (extension .dat for layout with xmgrace).*

*The orders necessary to the layout of curves are defined in the file forma03a.com 1.*

*One finds there:*

- *evolution of the component Sigma-Theta at moment 1 at the edge of the hole, and the curve definite by the analytical solution  $= P ([1+ 2\cos^2 ])$ ,*
- *evolution of the Syy component at the point G according to displacement at the same point, for every calculated moment,*
- *evolution of the resultant of the nodal forces on edge FG, according to displacement with not G.*

*These three calls to IMPR\_COURBE make it possible to generate three files, which can be traced via one*

*spreadsheet, or a software of layout of curve like xmgrace.*

*To plot a curve using xmgrace, “grace should be launched”, then “dated/ASCII importation/” and to select the file to be traced. For the moment, the file produced by Aster is not directly readable: it is necessary to comment on the lines of text (character #) before the reading by xmgrace.*

*One can visualize with GIBI, or GMSH the deformation, the isovaleurs of constraints SYY and of cumulated equivalent plastic deformation p. One will be able to note at moment 1. (elasticity) stress concentration at the point B. A moment 5.4, one can notice on the isovaleurs of cumulated plastic deformation, localization of the deformations in the vicinity of B.*

*One will be able to finally use interactive postprocessing Stanley to visualize fields or curves. It is enough for that to oter the character comment (# in front of the order to launching to Stanley.*

## **5 Modeling**

**B**

### **5.1**

#### **Characteristics of modeling**

*This modeling allows, within the framework of Practical Work, to conclude calculation until charge limit of the structure, thanks to the piloting of the loading and the discharge. The behavior is elastoplastic with isotropic work hardening given by a traction diagram such as the constraint uniaxial tends towards a constant value (6 MPa). There is thus a limiting load for this structure whose lower limit is known:  $P_{lim} > 5.4 \text{ MPa}$  [bib2].*

*The plate is subjected to a traction  $P$  following OY on side FG. Therefore, if  $P$  largely exceeds 5.4 MPa, it has there no more solution. Numerically, there are thus concern! It is what is observed: for  $P=5.4 \text{ Mpa}$ , convergence is very slow. If calculation were continued, there would be no more convergence with beyond 5.41 Mpa.*

*The best solution if one wishes to calculate the load limits (by the resolution of a problem elastoplastic incremental - other methods exist like the use of material incompressible with direct methods of analysis limits) is to use the piloting of the constraint imposed by the displacement of a point.*

**8/12**

**5.4**  
**Calculation until the limiting load**

**5.4.1 Test of increase in the loading to  $P = 5.4$  MPa**

**One wishes to continue calculation with an aim of considering a limit upper of the limiting load, in**

*trying to go beyond 5.4 MPa (limits lower analytical), without modification of the loading. One note whereas:*

- calculation is possible up to 5.41 Mpa, beyond that, it does not converge more, even by subdividing it no time,*
- convergence is increasingly slow.*

*The cause of difficult convergence is well the proximity of the limiting load. This is why it is necessary to subdivide the step of time. One can realize it by the value of the loading (5.4 Mpa = theoretical value of the lower limit) and by the curve constraint-displacement in top of the structure : one can note that for  $P=5.4$  MPa the limiting load is not completely reached (not of horizontal asymptote) but that one approaches some.*

*The isovaleurs of  $p$  show a zone of concentration of plastic deformation (comparable to one line of slip) tilted of  $53^\circ$  approximately compared to the vertical, energy of the point B at the flat rim This corresponds rather well to the theory which says that the lines of slip are tilted of  $54,44^\circ$  [bib2]. There is here of course an approximation of the line of slip which is in theory of null thickness.*

#### *5.4.2 Calculation with loading controlled by a displacement*

*A good way of carrying out this type of calculation is to use the piloting of the loading imposed by value of a displacement. It is thus proposed to modify the command file to use it piloting. One will be able to use for example displacement UY of point A to control constraint YY imposed on FG.*

*One will increase it up to 2 mm for example. One will take a coefficient equal to 1. One will thus be used*

*fictitious time  $T$  such as  $t = UY(A) \cdot 1$ . Thus time varies here between 0 and 2s (to represent one displacement between 0 and 2mm).*

*One treats all the rise charges some in a new STAT\_NON\_LINE. One can cut out the interval (0. 2.) in 10 or 20 increment for example.*

*The syntax of the key word factor PILOTING is:*

*PILOTING: \_F (GROUP\_NO = A, STANDARD = "DDL\_IMPO", NOM\_CMP = "DY", COEF\_MULT = 1.) )*

*Attention with the type of loading CH2 (force distributed): to use "FIXE\_PILO".*

*Note:*

*One could have controlled by the displacement of other points, e.g. Uy of the point G or UX of the point D.*

*To observe in the file “message” the value of the parameter: “ETA\_PILOTAGE”.  
One obtains in theory a good approximation of the limiting load (by higher value) than one  
will be able to compare on the analytical lower terminal (5.4).*

*One will be able to plot, in continuation, the curve forces resultant-displacement in G according to  
time. (them  
orders necessary are in the file forma03a.com 1). One should find on this curve  
value of the load limits given by “ETA\_PILOTAGE”.*

*One can visualize with GIBI, or GMSH the deformation, the isovaleurs of constraints SYY and of  
cumulated equivalent plastic deformation p. A moment 2, one can notice on the isovaleurs of  
cumulated plastic deformation, localization of the deformations in the vicinity of B.*

*One will be able to finally use interactive postprocessing Stanley to visualize fields or  
curves. It is enough for that to remove the character comment (# in front of the order of lancerment  
of  
Stanley.*

*5.4.3 Discharge: use of the elastic prediction and the elastic matrix*

*One will use initial calculation without piloting, in continuation since  $P = 5.4$  MPa. Several solutions  
are  
possible:*

*• Essayer to discharge with tangent matrix. Conclusion?*

- *Essayer the elastic prediction for the phase of discharge.*
- *Essayer MATRIX = “ELASTIC” (by increasing the iteration count total of Newton allowed).*

*To analyze the residual state: deformation, isovaleurs of constraints and variables internal.*

#### ***5.4.4 Use of linear research***

*If one wants to calculate all the way of loading (P growing up to 5.4 MPa, then decreasing up to 0) in same order STAT\_NON\_LINE, (without piloting), it is possible, with research linear and subdivision of the step of time (and stamps tangent reactualized).*

*One will be able to put 10 iterations of linear research, and to facilitate the phase of discharge, one will be able to put PREDICTION = “ELASTIC”.*

*One will be able to compare the solution obtained with that obtained previously (they must be identical!) and to compare time CPU and the iteration count of each solution.*

## **Discharge:**

*The way of loading goes up to 5.4 MPa then totals 0. One discretizes in 27 steps to go until  $P = 5.4$  MPa, and 6 steps to total 0. The consistent tangent matrix (FULL\_MECA) does not allow to converge at the time of the discharge. To treat the discharge, two methods can be used:*

*1) to calculate the discharge with elastic prediction (but reactualization of the tangent matrix with run of the iterations). One can note that that makes it possible to cross the phase of beginning of discharge. But that does not make it possible to calculate all the discharge (until a loading no one).*

*2) to use the elastic matrix. This method functions but convergence is slow. It is necessary simply to think of increasing the maximum iteration count (ITER\_GLOB\_MAXI).*

*Curve forces resulting - displacement: there is a state of residual stresses no one everywhere safe in some areas (around the point B in particular), but of the nonnull residual deformations.*

### **6.1.1 Use of linear research**

*With 10 iterations of linear research, and PREDICTION = "ELASTIC", one treats indeed all calculation in 100s approximately (instead of 85s without linear research, by cumulating all the stages the preceding ones, except piloting). One can in particular note that during the phase of discharge, the number*

*iterations is definitely weaker with piloting.*

***Summary of the results***

***This test makes it possible to go up how to carry out the calculation of an elastoplastic structure and sound***

***examination, and in particular to highlight the benefit to use piloting for one problem of limiting load.***

***One can retain of this test some ideas:***

- even apart from a perfect elastoplastic behavior, it can exist a limiting load:  
it is the case with all the real traction diagrams. It is then necessary to adapt the method of resolution with the mechanical solution and for example to use piloting,***
- cutting in small increments of load is often necessary to integrate correctly the relation of behavior. That can also contribute to convergence, it is thus advised to use the automatic recutting of the step of time,***
- linear research can be used to contribute to convergence, as well as the subdivision automatic of the steps of time.***

***SSNP116 - Coupling creep/cracking - Traction  
uniaxial***

***Summary:***

***This case of validation is intended to check the model of coupling of the laws of creep of Granger with the laws of plasticity/cracking. Coupling, initially restricted with some laws of the environment not linear of Code\_Aster, could be wide thereafter with more laws. Parameters of the models of plasticity/cracking is selected in a particular way to model an elastoplastic behavior quasi perfect, and to bring back itself to a problem presenting a relatively simple analytical solution.***

***The geometry consists of three linear elements (cubic and prisms in 3D, squares and triangles in 2D), and three quadratic elements, connected to the precedents by linear relations. Modelings tested here are modelings 3D, C\_PLAN, and D\_PLAN.***

***The loading is a uniaxial traction in imposed displacement.***

*One tests the coupling of the model of creep of Granger with BETON\_DOUBLE\_DP (or NADAI\_B in C\_PLAN), VMIS\_ISOT\_LINE and CHABOCHE. One has the analytical solution in 3D and C\_PLAN, when there is not variation in the temperature and drying. In cases 3D and D\_PLAN, one also tests the solutions obtained when there is variation in the temperature and the drying and activation of the corresponding withdrawals (with opposite effect). They are then tests of not-regression.*

## **Reference solution**

2.1

### **Method of calculation used for the reference solution**

*To be able to calculate a simple analytical solution, the following choices were carried out, the objective being*

*to validate the coupling and not the laws of plasticity/cracking or creep:*

.

*a law of creep of Granger with only one model of Kelvin in series,*

.

*a law of plasticity/cracking modelling a perfect elastoplastic law,*

.

*a loading of uniaxial traction.*

*The reference solution is calculated in an analytical way, knowing that in traction, only the criterion of traction is activated. The equations of the model are brought back to scalar equations allowing to calculate the analytical solution. The only difficulty comes from the determination of the beginning of plasticity*

*(moment and deformation of creep) which requires to solve by a numerical method an equation nonlinear with an unknown factor.*

*If the temperature is not constant, creep is more complex to solve, the solution analytical was not calculated. They are thus tests of not-regression. However, in the cases 3D and D\_PLAN, one can check that one obtains the same results with the 3 models.*

*The imposed deformation (displacement of an end of the structure) is a linear function of*

time allowing to bring into play creep and plasticity.

## 2.2

### Calculation of the reference solution

One notes, component  $\epsilon_{xx}$  of the total deflection,  $E$  component  $\epsilon_{xx}$  of the deformation rubber band,  $\epsilon_{fl}$  component  $\epsilon_{xx}$  of the deformation of creep of Granger, and  $\epsilon_{pl}$  component  $\epsilon_{xx}$  of plastic deformation, component  $\epsilon_{xx}$  of the constraint, and  $E$  the Young modulus.

The model of creep selected comprises one model of Kelvin in series and the model of plasticity/cracking is a nearly perfect law elastoplastic (quasi null slope of work hardening), which allows to easily calculate the analytical solution of the coupling creep/plasticity, in the case of one uniaxial simple traction. The nearly perfect elastoplastic law can be obtained starting from the laws of Code\_Aster BETON\_DOUBLE\_DP or NADAI\_B, VMIS\_ISOT\_LINE or CHABOCHE, by choosing it set of parameters which is appropriate (work hardening quasi no one).

The loading is a uniaxial traction in imposed displacement. A deformation is thus imposed total proportional to passed time, of the form

$$\epsilon_{xx} = T$$

.  
0.  
. Like there is no exerted effort

in the other directions, the stress field is uniaxial. One can thus bring back oneself to one problem 1D for the resolution, which makes it possible to calculate in the second time of the deformations

in the transverse directions with the loading ( $\epsilon_{yy}$  and  $\epsilon_{zz}$ ).

$$\begin{pmatrix} \epsilon_{xx} \\ \epsilon_{yy} \\ \epsilon_{zz} \end{pmatrix} = \begin{pmatrix} T \\ 0 \\ 0 \end{pmatrix} \text{ and } \begin{pmatrix} \sigma_{xx} \\ \sigma_{yy} \\ \sigma_{zz} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

### **Resolution in linear elasticity**

Before reaching the threshold of plasticity, the plastic deformation is null, which leads to:

$\epsilon = 0$  (imposed traction)

$$\epsilon = \frac{\sigma}{E} + \frac{\sigma}{K}$$

$\epsilon = \frac{\sigma}{E} + \frac{\sigma}{K}$  with  $\mu = S$  and  $K =$

$$\epsilon = \frac{\sigma}{E} + \frac{\sigma}{K}$$

One obtains the differential equation allowing to calculate the deformation of creep:

$$\dot{\epsilon} = \frac{\sigma}{E} + \frac{\sigma}{K}$$

The deformation of creep is thus expressed as the sum of a linear function of time and one exponential function, of the type:

$$\epsilon(t) = \frac{\sigma}{E} + \frac{\sigma}{K} \left( 1 - e^{-\frac{t}{\tau}} \right)$$

who gives in the differential equation:

$$0 = \mu \cdot \epsilon(t) + K \cdot (\epsilon(t) - \epsilon_0)$$

$() = T$

$() =$

$T +$

$1-$

$E$

$E$

$E$

$K + E$

$(K + E) 2$

The components  $yy$  and  $zz$  of the elastic strain and creep are obtained by multiplication of component  $xx$  by the Poisson's ratio.

Component  $xx$  of the constraint is worth:  $= E$

$. E = E (- fl)$

That is to say:

$2$

$K +$

-

$$\begin{aligned} &E T \\ &\cdot K.E \\ &\cdot E \mu \\ &\cdot \\ &0 \\ &0 \\ &\mu \\ &T \\ &() = T \\ &() = \\ &T + \\ &1- \\ &xx \\ &E \\ &K + E \\ &(K + E)^2 \end{aligned}$$

**Threshold of elasticity**

*The behavior remains elastic until one reaches limited of elasticity. In the case of one uniaxial traction, the equivalent constraint is equal to the nonnull component of the constraint. plasticity thus intervenes when  $\sigma_x$   $T$*   
 *$\sigma_x = \sigma_y = \sigma_z = f_t$  (resistance in traction), is:*

$$\begin{aligned} &K + E \\ &2 \end{aligned}$$

$$\begin{aligned} &- \\ &T \\ &\cdot K.E \\ &\cdot E \mu \\ &\cdot \\ &0 \\ &0 \\ &\mu \\ &T + \\ &1- \\ &= \end{aligned}$$

$$\frac{K + E}{(K + E)E} \frac{ft}{2}$$

*This equation, solved by a numerical method, makes it possible to obtain the moment of the beginning of plasticization  $t_{plas}$  and deformation of creep at this moment:*

$$K + \frac{E}{T}$$

$$\frac{t_{plas}}{E} \cdot E$$

$$\mu_{plas} \mu$$

$$= T \left( \frac{f_l}{f_l} \frac{t_{plas}}{T} \right) = \frac{1}{E}$$

$$\frac{K + E}{-} \frac{t_{plas}}{K + E}$$

**Resolution in plasticity**

The model of plasticity was selected in order to obtain a simple analytical resolution. It is about a law of nearly perfect plasticity, obtained by taking a particular play of parameters for the model of behavior leading to a quasi null slope of work hardening. Therefore, in plastic phase, constraint (component  $\sigma_x$ ), equal to the equivalent constraint is worth resistance in traction. equations of the model are then:

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

with like initial conditions:

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

$$\sigma = \sigma_0 + \mu \sigma_0 \left( \frac{\sigma}{\sigma_0} \right)^n$$

what leads to the differential equation making it possible to calculate the deformation of creep:

$\dot{\epsilon} = \mu \dot{\epsilon} + K \dot{\epsilon}$

## **5 Modeling**

### **B**

#### **5.1**

##### **Characteristics of modeling**

##### ***D\_PLAN (1 QUAD4, 2 TRI3, 1 QUAD8, 2 TRI6)***

*They are a square with 4 nodes and two triangles with 3 nodes bound by linear relations to a square with 8 nodes and of two triangles with 6 nodes. The unit is subjected to a uniaxial traction according to direction X. Dimensions following there are unit. Dimensions according to direction X are chosen so that all the elements have the same characteristic length (root of surface for the quadratic elements, and root of the surface multiplied by 2 for the elements linear).*

*The stress fields and deformations are uniform.*

*In 2D plane deformations (D\_PLAN), one tests the coupling between law BETON\_DOUBLE\_DP with law GRANGER\_FP. One tests also the coupling of laws VMIS\_ISOT\_LINE with law CHABOCHE and GRANGER\_FP. The analytical solution was not calculated in D\_PLAN.*

***Results of modeling C***

***8.1 Values***

***tested***

*Were tested components  $\epsilon_x$  of the field and stress field SIEF\_ELNO\_ELGA of deformations of creep EPGR\_ELNO. For the coupling with law NADAI\_B, these values were tested at the C1 point located at the interface enters the linear elements and the quadratic elements, and at the F1 point located at the end of the structure, where is applied imposed displacement (in  $x_{max}$ ).*

*For the coupling with the other laws, (VMIS\_ISOT\_LINE and CHABOCHE), the fields were tested only at the F1 point located at the end of the structure.*

*As for the case 3D, one carries out the first calculation with temperature and constant drying, which allows to validate NADAI\_B in plane constraints. All the models are then tested with temperature and drying variables and activation of the corresponding withdrawals. It is checked that the same ones well are found results with VMIS\_ISOT\_LINE and CHABOCHE that with NADAI\_B.*

*The tests are carried out at moment 10, when plasticity did not start, only creep is present, and at moment 100, after the beginning of the plasticization of the concrete.*

**9**  
***Summary of the results***

*If one knows the analytical solution (not-variation of the temperature and drying), it case test offers very satisfactory results with a lower deviation than 0.02% for all the cases of calculation. The iteration count for the plastic phase is generally about ten; for the model of CHABOCHE, convergence are better with an elastic matrix. This is explained by the choice of the law of nearly perfect plasticity, obtained with models VMIS\_ISOT\_LINE and CHABOCHE, and with particular plays of parameters. In fact, these same models used without coupling creep/cracking, under the same conditions of loading and with the same ones parameters, present the same difficulties of convergence.*

*It is checked that under the effect of the increase in the temperature the deformations of creep are increased (+ approximately 3% in the elastic phase, +23% in the plastic phase).*

*Lastly, in 3D and C\_PLAN, one checks that the 3 models which were degenerated give many quasi-similar results. On the other hand, in D\_PLAN, model BETON\_DOUBLE\_DP is not equivalent with the two other models because of writing of the criterion which depends on the trace of the tensor deformations and is thus not equivalent to the perfectly plastic model.*

## ***FORMA04 - Mechanical adaptive grid on one beam in inflection***

### ***Summary:***

***In this case-test, it is a question of making sure of the not-regression of the TP n°1 associated Indicating courses the “of error and adaptation of grid; State of the art and establishment in Code\_Aster” of the formation “Non-linear static Analysis with Code\_Aster”.***

***In fact, one “abuses” an elastic design on a metal beam in inflection in forced modeling plane. One makes it converge uniformly via the tool of refinement-déraffinement HOMARD® encapsulated in MACR\_ADAP\_MAIL, then freely by coupling the process with a chart of space errors (exhumed via CALC\_ELEM “ERRE\_ELGA\_NORE” or “ERRE\_ELEM\_NOZ1”) localised on each finite element.***

***From a data-processing validation point of view, this case test of course makes it possible to test the not-regression of different coupling calculations from chart of errors/procedure of refinement-déraffinement in mechanics, but also options the “pre one and postprocessings” of these calculations (smoothing of the constraints to the nodes, passage of an error by element with an error with the nodes by element).***

***Each modeling is associated a question of the TP and one retranscribed “substantial” marrow of it elements of correction. Entirety of the text of the TP being available on Internet site <http://www.code-aster.com/utilisation/formations>.***

## ***Reference solution***

### ***2.1***

#### ***Method of calculation used for the reference solutions***

***On such a case of figure, it is not possible to exhume an analytical solution! The solution of reference used for error analyses on the arrow and the potential energy of deformation is in fact an approximate solution obtained after a series of four uniform refinements (on even grid but in TRIA6).***

***This procedure of uniform refinement can be controlled by a loop PYTHON and the operator UNIFORM MACR\_ADAP\_MAIL option. The first two modelings are precisely one illustration of this functionality.***

### ***2.2***

#### ***Result of reference***

***Potential energy of deformation = 0.102242 J***

***Arrow  
= 0.0614777 m***

### ***2.3***

#### ***Uncertainty on the solutions***

***They acts only of approximate solutions obtained on a “quasi-converged” grid.***

### **3 Modeling**

**With**

#### **3.1**

##### **Characteristics of modeling**

**The grid is carried out with elements of the type TRIA3. Calculation is made in linear elasticity with operator STAT\_NON\_LINE.**

**One calculates the charts of space errors of the indicator of Zhu-Zienkiewicz version 1 (ERRE\_ELEM\_NOZ1) and of the indicator in pure residue (ERRE\_ELGA\_NORE). Beforehand it is necessary to have**

**smoothed the stress field of the points of Gauss to nodes (SIEF\_ELNO\_ELGA) and, for post-treat the chart of error (via GIBI), it is necessary to transform it of a CHAM\_ELEM by element with a CHAM\_ELEM**

**with the nodes by element. One determines also the value of the arrow (POST\_RELEVE\_T) and energy**

**potential of deformation (POST\_ELEM).**

**The whole is placed in a loop PYTHON allowing the installation of a procedure of uniform refinement in nb\_calc=4 levels (via MACR\_ADAP\_MAIL option UNIFORME=' RAFFINEMENT').**

**One can thus note the convergence of the values of arrow and energy, the increase of theirs errors relative compared to the errors provided by the indicators (they same into relative and on all the structure), variations of the indices of effectiveness of the indicators and their good checking of the assumption of saturation.**

*In order to illustrate councils of “good practice” for the quality of the studies, on the aspects geometry with a grid, grid itself and standard of finite elements, one uses the options **adhoc LIRE\_MALLAGE**, **MACR\_ADAP\_MAIL** and **MACR\_INFO\_MAIL**.*

***converge optimalement the grid makes it possible to make.***

*The quality of the elements is impacted little by the process of refinement/déraffinement. Count held of the choices operated in HOMARD®, it can even improve in 3D!*

***The type of indicator and its mode of standardization affect great the final grid.***

*Taking into account the type of standardization adopted for the indicators in mechanics,*

*(K)*

*(K) = 100 ×*

*(in %)*

*rel*

*2*

*2*

*(K) + H 0, K*

*On problems with singularities (embedding, discontinuity of curve, returning corner, fissure....), it is to better use the absolute component of these indicators. Because as for “our good old woman fixed beam”:*

*(K)*

*% when*

*(close to embedding)*

*H*

*rel*

*0*

*0, K*

*(K)*

*% when*

*(close to the arrow)*

*H*

*0*

*rel*

*100*

*0, K*

*and this, independently of the true values of the absolute indicator (K)!*

*This does not call at all into question the great utility of these indicators. It is just necessary to take account of*

*these elements to refine its diagnosis and “to possibly juggle” with these two components to refine in the zones of interest.*

***The problem does not arise in thermics, because the indicator in residue for the thermal problem is standardized differently. One can however “juggle” with the components of the indicator thermics and of the limiting, “fictitious” conditions or not, to direct the construction of a grid refined or déraffiné by zones (cf [§6.3] [R4.10.03] and modeling A, \_ TP21 \_ of [V6.03.120]).***

## **Summary of the results**

*In this case-test, it is a question of making sure of the not-regression of the TP n°1 associated the courses*

**“Indicating of error and adaptation of grid; State of the art and establishment in Code\_Aster”** of the formation “Analyzes static non-linear with Code\_Aster”.

*In fact, one “abuses” an **elastic design on a metal beam in inflection** in modeling plane constraint. One makes it **converge uniformly** via the tool of refinement-déraffinement HOMARD® encapsulated in MACR\_ADAP\_MAIL, then **freely** by coupling the process with a chart errors space (exhumed via CALC\_ELEM + “ERRE\_ELGA\_NORE” or “ERRE\_ELEM\_NOZ1”) located on each finite element.*

*The objectives of this TP are multiple, it acts:*

- *to familiarize and put into practice the two dual problems: calculation of chart of indicator of error and strategies of adaptation of grid. On standard cases, but also on pathological cases...,*
- *to detail the various parameter settings of accused operators (CALC\_ELEM, MACR\_ADAP\_MAIL) and related operators who can appear particularly interesting for these problems (INFO\_MAILLAGE, MACR\_INFO\_MAIL, PROJ\_CHAMP...),*
- *to hammer councils of “good practice” for the quality of the studies and the use of tools already available on the subject. One is interested only in the aspects geometry with a grid, grid itself and standard of finite elements. One is not delayed here on the problems of no time, of calibration of numerical parameters and on the aspects sensitivity opposite data,*
- *to illustrate the formidable potentialities and facilitated which allows the coupling “language*

*ASTER/PYTHON” in the command file of a study (test, buckles, posting, calculation, personal macro-order, interactivity...). Official case-tests being gauged for to function in batch, some of these aspects “were thus commentarisés” in the file of order.*

*From a **data-processing validation** point of view, this case test of course makes it possible to test the not-regression of various couplings calculations of chart of errors/procedure of refinement-déraffinement in mechanics, but also options the “pre one and postprocessings” of these calculations (smoothing of the constraints with nodes, passage of an error per element with an error with the nodes by element).*

*Each modeling is associated a question of the TP and one **retranscribed the “substantial one” marrow of the elements of correction**. Entirety of the text of the TP being available on Internet site <http://www.code-aster.com/utilisation/formations>.*

*The grid is carried out with elements of the type TRIA3. Calculation is made in linear thermics stationary isotropic with operator THER\_LINEAIRE in lumpé (modeling PLAN\_DIAG).*

*One calculates the charts of space errors of the indicator in pure residue (ERTH\_ELEM\_TEMP). Beforehand it is necessary to have smoothed the heat flux of the points of Gauss to the nodes (FLUX\_ELNO\_TEMP) and, post-to treat the chart of error (via GIBI), it should be transformed of one*

*CHAM\_ELEM by element with a CHAM\_ELEM with the nodes by element. One determines also the value of*

*the integral of the temperature on GM35 (POST\_RELEVE\_T) and that of the potential energy of deformation (POST\_ELEM).*

*The whole is placed in a loop PYTHON allowing the installation of a procedure of free refinement in nb\_calc=4 levels (via MACR\_ADAP\_MAIL option LIBRE='RAFF\_DERA') coupled on the chart of error exhumed beforehand. One controls this process by the component ERTREL of ERTH\_ELEM\_TEMP (component relative of the indicator in residue). With like criteria CRIT\_RAFF\_PE=0.2 and CRIT\_DERA\_PE=0.1 (one refines 20% of the worst elements and one déraffine 10% of best).*

*One can thus note the convergence of the values of the temperature and energy, the increase of their errors relative compared to the errors provided by the indicator (they same into relative and on all the structure), variations of the indices of effectiveness of the indicator and its good checking of the assumption of saturation.*

*In order to illustrate councils of “good practice” for the quality of the studies, on the aspects geometry with a grid, grid itself and standard of finite elements, one uses the options adhoc LIRE\_MALLAGE, MACR\_ADAP\_MAIL and MACR\_INFO\_MAIL.*

***What it was necessary to retain of this part of the TP...***

*It is necessary well to keep in mind, that as a “simple postprocessing” of the problem thermomechanical, the **indicator cannot unfortunately provide more reliable diagnosis in the zones where the resolution of the initial problem stumbles** (crack, corners, multi-material, embedding, shock...). It is thus necessary to begin a process of adjustment (UNIFORM or FREE), with a grid refined already a little “with the hand” close to the zones of discontinuities (materials, geometrical...).*

*MACR\_ADAP\_MAIL does not have process of regularization, therefore a bad initial grid will produce, even coupled to an indicator, probably a bad adapted grid!*

*As in mechanics, the sequence “operators thermique/MACR\_ADAP\_MAIL OPTION “FREE”” converge optimalement the grid makes it possible to make.*

*One can, moreover, “to juggle” with the components of the thermal indicator and the conditions limits, “fictitious” or not, to direct the construction of a grid refined or déraffiné by zones (cf [§6.3] [R4.10.03]).*

***6.2******What it was necessary to retain of this part of the TP...***

*Into thermomechanical, various strategies of adaptation of grid are offered to the user:*

- to adapt the grid only according to one thermal criterion,*
- idem according to a mechanical criterion,*

- to adapt initially according to a thermal criterion, then according to a mechanical criterion (two separate loops of adaptation).
- to adapt jointly according to a thermal criterion then mechanical (a loop as in this TP),
- to adapt according to a thermomechanical criterion.

In Code\_Aster, one does not have access to explicitly thermomechanical indicators, although the mechanical indicators can comprise incidentally a thermal dependence via loading TEMP\_CALCULEE.

According to the needs for the study (rather thermal or rather mechanics, to make converge a grid broadly, better taken into account of certain CLs...) one can set up in the code, one of the first four strategies.

**Good practice during a thermomechanical calculation being to use the P1 elements lumpés in thermics and P2 in mechanics, that resulted in using two grids (as in this TP) and to interpolate the thermal field linear solution on the quadratic mechanical network (via PROJ\_CHAMP).**

Nevertheless, if one wishes to work only with one grid, one can easily decline one of quatres first strategies via option MAJ\_CHAMP of MACR\_ADAP\_MAIL. That allows, all in adapting the grid according to a thermal criterion (resp. mechanics), to update the field complementary, mechanical (resp. thermics), on the new adapted grid.

**Summary of the results**

*In this case-test, it is a question of making sure of the not-regression of the TP n°2 associated the courses*

**“Indicating of error and adaptation of grid; State of the art and establishment in Code\_Aster”** of the formation “Analyzes static non-linear with Code\_Aster”.

*In fact, one “abuses” a **thermoelastic calculation on a metal cylinder head fissured** in plane forced modeling (for the mechanical part) and lumpé (for the thermal part).*

*In accordance with the “good practices” of quality type of the studies, one uses two grids distinct: linear in thermics and quadratic in mechanics.*

*One first of all carries out (modeling A) the thermal calculation on which one makes converge freely it P1 grid with a coupling chart of indicator of space errors (CALC\_ELEM + “ERTH\_ELEM\_TEMP”) /RAFFINEMENT-DÉRAFFINEMENT (MACR\_ADAP\_MAIL “RAFF\_DERA”).*

*In the second modeling (B), the two grids are adapted jointly according to the same one process during a chained thermomechanical calculation. For the free adaptation of the grid mechanics, one has recourse to the indicator in pure residue “ERRE\_ELGA\_NORE”.*

*The objectives of this TP are multiple, it acts:*

- *to familiarize and put into practice the two dual problems: calculation of chart of indicator of error and strategies of adaptation of grid. On standard cases, but also on pathological cases and for chainings of calculations,*
- *to detail the various parameter settings of accused operators (CALC\_ELEM, MACR\_ADAP\_MAIL) and related operators who can appear particularly interesting for these problems (INFO\_MALLAGE, MACR\_INFO\_MAIL, PROJ\_CHAMP...),*
- *to hammer councils of “good practice” for the quality of the studies and the use of tools already available on the subject. One is interested only in the aspects geometry with a grid, grid itself and standard of finite elements. One is not delayed here on the problems of no time, of calibration of numerical parameters and on the aspects sensitivity opposite data,*
- *to illustrate the formidable potentialities and facilitated which allows the coupling “language ASTER/PYTHON” in the command file of a study (test, buckles, posting, calculation, personal macro-order, interactivity...). Official case-tests being gauged for to function in batch, some of these aspects “were thus commentarisés” in the file of order.*

*From a **data-processing validation** point of view, this case test of course makes it possible to test the not-regression of*

*various couplings calculations of chart of errors/procedure of refinement-déraffinement into thermo mechanics, but also options the “pre one and postprocessings” of these calculations (smoothing of constraints and of the heat fluxes to the nodes, passage of an error per element with an error with nodes by element).*

*Each modeling is associated a question of the TP and one **retranscribed the “substantial one” marrow of the elements of correction**. Entirety of the text of the TP being available on Internet site <http://www.code-aster.com/utilisation/formations>.*

### ***14.2 Notice***

***The surface of contact slave is with a grid in TRIA6 and the surface of main contact is with a grid in QUAD8. A use with elements QUAD8 for surface slave and of the TRIA6 for surface main does not satisfy the conditions of compatibility necessary to the good integration of terms of contact [R5.03.52]. In a general way, if one does not apprehend correctly this concept of compatibility, one advises with the user not informed to use the same elements for main grid of surfaces and slave.***

## **15 Modeling**

### **G**

#### **15.1 Characteristics of modeling**

*One uses a modeling 2D\_PLAN for the solid elements with the method CONTINUES for treatment of CONTACT with integration of the type “SIMPSON2”.*

*Plate 2 is subjected to a pressure  $E = 1.105 \text{ Pa}$  on all surface CD. This pressure to a displacement imposed  $U0 = 0.1 \text{ m}$  is equivalent on CD according to following formulas':*

*$= U0/HD = - 0.1/2$  and  $P0 = E = 1.105 \text{ Pa}$*

**Note:**

*It should be taken care of the orientation of the group of mesh of plate 2 in such way that the normal that is to say outgoing. One had to use key word ORIENT\_PEAU\_2D.*

**Note:**

*In this modeling, one imposes a pressure on plate 2. So that the problem is soluble, it is necessary CONTACT\_INIT = “YES”. In the contrary case, with the first iteration of first step of time, plate 2 would have a rigid movement of body.*

## ***24.2 Notice***

***The surface of contact slave is with a grid in TRIA3 and the surface of main contact is with a grid in QUAD8. A use with elements QUAD4 for surface slave and of the TRIA6 for surface main does not satisfy the conditions of compatibility necessary to the good integration of terms of contact [R5.03.52].***

## ***25 Summary of the results***

***One seeks on this example very simple to test a new technique of integration of the terms of contact based on the subdivision by subelements available only for the method “CONTINUOUS”. This technique aims to attenuate the amplitude of oscillation of the pressure of contact. In the case studied here, the pressure is constant on all the surface of contact (notice that the Poisson's ratio is null).***

***One also implemented a new diagram of integration of the Newton-Dimensions type allowing of to solve the problems of contact for Linear/Quadratic mixed elements with incompatibility of grids.***

***One notes thus that with the methods “FORCED” and “PENALIZATION” the solution present nonphysical oscillations of about 6 to 7%. By using the “CONTINUOUS” method, them oscillations disappear almost completely and the results obtained are very close to the solution of reference (<0,5%). Moreover, one notes that when this technique is used, the interpenetration (due to the use of master-slave modeling) decreases also significantly. The “CONTINUOUS” method allows moreover a nonapproximate treatment of surfaces of contact with a grid with quadratic elements, whereas the “FORCED” method is used with one linearization of the elements on the surface of contact. One advises with the users not informed on compatibility of the elements to be used for the main grid of surfaces and slave to use the same one type of meshes for two surfaces.***

***SSNP122 - Traction. Model of Rousselier in  
versions local and nonlocal***

***Summary:***

***This quasi-static test consists in applying to a bar a loading of traction. Two versions are used  
model of Rousselier with the kinematics of the great deformations of Simo and Miehe: the local  
version and***

***the nonlocal version (model with gradient of internal variables). For a test tensile, terms in  
gradient are not activated: one thus finds the results of the local version, at least as long as the  
solution***

***local version remains homogeneous (not localization).***

***The bar is modelled by a quadrangular element (QUAD8) in plane deformation.***

***The results obtained are results of nonregression. The two models give identical results  
as long as the solution of the local version does not locate. The solution of the model with gradient  
remains homogeneous all  
with the length of the way of loading.***

 $T(S)$   
1.5  
1 2*

## *1.4 Conditions initial*

*Null constraints and deformations with  $T = 0$ .*

## *2 Results of reference*

*We do not have reference solution.*

*· As long as the solution of the local model remains homogeneous for the various points of Gauss, i.e. for  $t=0.93s$ , one will take as reference solution the results obtained with Code\_Aster for this model. For the results of the model with gradient, one must find exactly results obtained with the local version. At this moment, one will thus test, for two models, the constraint of Cauchy  $yy$  in the direction  $y$ , the constraint of Cauchy  $zz$  in direction  $Z$ , cumulated plastic deformation  $p$  and the porosity  $F$ , calculated at the point of Gauss  $n^{\bullet}1$  of the mesh [1,2,3,4].*

*· For the model with gradient, the answer must remain homogeneous in the points of Gauss all with length of the way of loading. To test this result, one will adopt as solution of reference, the constraint of Cauchy  $yy$  in the direction  $y$  at the points of Gauss  $n^{\bullet}1, 2, 3$  and 4 mesh [1,2,3,4] and at the final moment.*

***SSNP123 - Plate notched in elastoplasticity (test elements QUAD4 under integrated)***

***Summary:***

***This test 2D in plane deformations quasi-static makes it possible to illustrate the questions relating to the incompressibility during the use of an elastoplastic law of behavior: when the rate of plasticity becomes important, of nonphysical oscillations of constraints can appear. It is shown that the use of elements QUAD4 under integrated can allow to mitigate this problem.***

***It is about a notched rectangular plate made up of an elastoplastic material with isotropic work hardening who is subjected to a traction at his ends. One is interested in the elastoplastic solution in load.***

***Modeling A corresponds to the use of elements QUAD4 under integrated stabilized by the method “assumed strain”.***

***Modeling B corresponds to the use of the incompressible elements QUAD8 which make it possible to obtain one reference solution.***

**Summary of the results**

**The result obtained using elements QUAD4 under integrated stabilized by the method assumed strain is very close to that provided by the incompressible quadratic elements, as it can to note on the graph below. This graph gathers the results for various elements:**

**QUAS4 elements QUAD4 under integrated**

**QUAD4 traditional elements QUAD4**

**QUAD8 traditional elements QUAD8**

**QUAS8 quasi incompressible elements QUAD8**

**One thus notes the good quality of the solution given by elements QUAD4 under integrated and disappearance of the oscillations of constraints given by traditional elements QUAD4.**

***SSNP126 - Validation of the law of behavior***  
***JOINT\_BA (steel-concrete connection) in plane 2D***

***Summary:***

***Validation of the law of behavior JOINT\_BA of the connection steel concrete by using the element of joint 2D plan. This joined element is embedded in two nodes and bound to an element cubes with the characteristics of one unspecified elastic material. By applying a monotonous loading in slip to the cubic element, one check the degradation of the interface, as well as the passage of the small deformations at the beginning of the experiment, with the great observable slips starting from the peak of the resistance of the connection. In this case test, them parameters used do not correspond to the data of a particular experimental case. However, validation is carried out by comparison with results obtained with code FEAP of Professor Taylor, from Berkeley, software in which this formulation was established.***

***Summary of the results***

*The comparison of the results resulting from Code\_Aster and those obtained numerically by code FEAP of Professor Taylor of Berkeley are satisfactory (the maximum change is 2.18% on constraints).*

*The objective of modeling is to test the stability of the law of behavior by using them already existing elements joined in Code\_Aster: one can consider that the establishment of the law is correct. However, since the maximum resistance of the connection between the steel reinforcements and the concrete is reached beyond the framework of the small deformations, it is necessary to pay attention to the choice of increments of time in particular when JOINT\_BA is used in combination with other laws of behavior nonlinear (law MAZARS, for example).*

***SSNP128 Validation of the element with discontinuity  
on a plane plate***

***Summary:***

***The goal of this test is of exhiber an analytical solution in order to validate the quality of the element with discontinuity (see documentation [R7.02.12] for details on this element). The objective of this test is to check that this model conduit with a good prediction of the value of the jump of displacement along a crack. With this intention, one seek an analytical solution presenting a nonconstant jump along a discontinuity which one compares with the solution obtained numerically. In addition when one seeks to validate a numerical method it is preferable to ensure itself of the unicity of the required solution. We will see that it is the case for the solution analytical presented if a condition relating to the maximum size of the field studied according to parameters of the model is checked.***

## **2.1 Solution analytical**

*The function of Airy (X, y) controlled by the equation  $\Delta^2 u = 0$  on, if efforts outsides are null, leads to constraints satisfying the compatibility and equilibrium equations in elasticity (see Fung [bib1]). Components of the constraint, and derive from*

$\sigma_{xx}$

$\sigma_{yy}$

$\sigma_{xy}$

$(X, y)$  in the following way:

$\sigma_{xx}$

$\sigma_{yy}$

$\sigma_{xy}$

$\sigma_{xx}$

$\sigma_{yy}$

and  $\sigma_{xy} = -$

$\sigma_{xx}$

**2.1-1**

$\sigma_{xx}$

$\sigma_{yy}$

$\sigma_{xy}$

$\sigma_{xx}$

$\sigma_{yy}$

$\sigma_{xy}$

$\sigma_{xx}$

$\sigma_{yy}$

$\sigma_{xy}$

*Let us choose a function Bi-harmonic (X, y) defined by:*

3

$$\frac{1}{2} \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) = \frac{1}{2} \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) + \frac{1}{2} \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

with, and arbitrary real constants. One deduces some according to [éq 2.1-1] the field from constraint:

$$u = X + y + \frac{1}{2} x^2$$

$$= 0$$

**éq 2.1-2**

$$y^2$$

$$= -y - \frac{1}{2} xy$$

By integrating the elastic law, if one notes  $E$  the modulus Young and the Poisson's ratio (that one takes no one), one deduces the field from it from displacement in checking balance:

$$\frac{1}{2} x^2 - y^2 + X (y + \frac{1}{2} x^2) = U(X, y) + \frac{1}{2} E$$

$$2$$

$U = ^$

$\epsilon q$

5/8

*Respectively let us note  $U_0$  and  $U$  the displacements on 0 and 0 given by [  q 2.1-3]. These the last correspond to the boundary conditions leading to the stress fields [  q 2.1-2]. With to start from these data, it is easy to build a field of displacement with a discontinuity on*

the edge. Indeed, knowing the normal constraint  $\mathbf{n}$  on which one notes  $\mathbf{F}(y)$ , one obtains it

0

0

jump of displacement  $(y)$  by reversing the exponential law of behavior of Barenblatt type:  
 CZM\_EXP (see documentation on the elements with internal discontinuity and their behavior:  
 [R7.02.12]):

$G \mathbf{F} y$

$\mathbf{F} y$

$C$

$( )$

$(y)$

$( )$

$= -$

$\mathbf{F} y$

$C$

$( ) \ln$

$C$

for all  $y$  in  $[0, H]$ . Thus, the new displacement imposed on generating such a jump is equal

0

with  $\mathbf{U}^-$ . One thus built an analytical solution of the plane plate checking the equations

0

of balance and compatibility with a discontinuity in 0 along which the jump of displacement  
 is not constant. Let us point out the boundary conditions of the problem:

$\mathbf{U} = \mathbf{U}(X, y)$  on 0

éq

2.1-4

$\mathbf{U} = \mathbf{U}^0(y) - (y)$  on 0

2.2

**Unicity of the solution**

After having built an analytical solution it is important to make sure that the latter is single  
 to be able to compare it with the numerical solution. One shows, to see [bib2], that unicity is guaranteed

as soon as the following condition, on the geometry of the field like on the parameters material, is checked:

$2 G$

$\mu C$

$L <$

.

**éq 2.2-1**

$2$

$C$

Dimensions of the plate and the parameters material previously given check this condition.

## **3 Modeling**

**With**

### **3.1**

**Characteristics of modeling**

*The idea is to carry out a digital simulation corresponding to the problem presented in the part the preceding one and to compare the results obtained. The elements with discontinuity allow to represent the crack along 0. The latter have as a modeling PLAN\_ELDI and one behavior CZM\_EXP. The other elements of the grid are elastic QUAD4 in modeling D\_PLAN.*

*The values of the parameters of the function of Airy for the construction of the analytical solution are taken arbitrarily:*

$$\begin{aligned} & -1 \\ & -1 \\ & = 0 \text{ MPa.mm}, = 1 \text{ 4 MPa.mm}, = 1 \text{ 2 MPa and } = 0 \text{ MPa} \end{aligned}$$

### 3.2

#### **Characteristics of the grid**

*One carries out a grid of the plate structured in quadrangles with 20 meshes in the width and 50 in the height. One has the elements with discontinuity along the with dimensions 0 with the normal uur directed according to - X. This is carried out using key word CREA\_FISS of CREA\_MAILLAGE (see documentation [U4.23.02]).*

### 4

#### *Summary of the results*

*These results enable us to conclude that the element with internal discontinuity leads to good*

*approximation of the analytical solution. Moreover, one study on the dependence with the grid was realized in [bib2]. It is noted that the error made on the jump of displacement decrease when one refines grid. That makes it possible to conclude that, in spite of a constant jump by element, this model allows to correctly reproduce a crack with a nonconstant jump by refining the grid.*

### 1.3

#### *Boundary conditions and loadings*

*The loading is of displacement type imposed in a point located at the center of the pin which is modelled by four indeformable angular sectors. The temperature is imposed constant on the whole of the test-tube ( $T = 35^{\circ}\text{C}$ ). Half of the test-tube being modelled, a condition of symmetry is applied to the ligament located behind the notch.*

## 2

### *Reference solution*

#### 2.1

#### *Method of calculation used for the reference solution*

*The notch is made of a half-circle of ray  $R$  located in bottom of crack and of a fine zone representing the beginning of the ligament of the defect which will be represented by a zone of grid of the type “chips”. One determines at every moment the evolution of the quantity  $G_p(L)$  defined by:*

$$G_p(L) = \frac{2 W_{elas}(L)}{L}$$

*where  $W_{elas}(L)$  is the elastic energy calculated on the formed zone of “chips” located behind melts of notch and length  $L$ . One must then calculate the maximum of this quantity compared to  $L$ , that one calls “ $G_p$ ”.*

$$G_p = \frac{\{ \text{Max } G_p(L) \}}{L}$$

*The moment criticizes where the propagation of the defect will start is then that where  $G_p$  reached the breaking value*

**“Gp crit”.**

**SSNP303 - Element in plane constraint and traction -**

**Perfect plasticity**

**Summary:**

***This test of quasi-static mechanics nonlinear 2D consists in charging three superimposed elements of plate***

***(type of element mecpqu4). The 4 nodes are common to the 3 elements. The elements have properties different (perfect plasticity) to obtain a suitable traction diagram. This test is drawn from the guide NAFEMS.***

***The goal is to compare the various methods of the Newton-Raphson type making it possible to solve the system***

***nonlinear equations (NEWTON: ("ELASTIC" MATRIX) and NEWTON: ("TANGENT" MATRIX) with REAC\_INCR and REAC\_ITER). The selected criterion of convergence corresponds to 0.01% of the residual force***

***(RESI\_GLOB\_RELA).***

***Modeling is carried out with plane elements of type MECPQU4.***

**SSNP305 - Element of bar in compression -**

**Appearance of a negative pivot**

**Summary:**

This test of quasi-static mechanics linear 2D consists in charging an element of bar in compression. Of

one

side, the element is fixed according to the degrees of translation on a node. Other side, the element is fixed according to

the second degree of translation on a node in order to model the slip along a line. With some moment the stiffness becomes negative (= negative slope). This test is drawn from guide NAFEMS (analytical solution).

The structure will be charged by using a piloting by displacement.

The plate is modelled by 12 plane elements (MECPQU4). The material has a linear behavior and one takes into account nonthe geometrical linearities. One uses the key word factor “COMP\_ELAS” option “GREEN”.

***SSNP311 - Biblio\_131. Cracking in mode II of one elastoplastic test-tube***

**Summary:**

*This test results from the validation independent of version 3 in breaking process.*

*It is about a two-dimensional test in statics which aims at the validation of the calculation of G, and its not dependence with respect to the crown, in elastoplastic mode in an incremental calculation, on a geometry noncommonplace. The law of behavior used is an elastoplastic law of Von Mises with isotropic work hardening.*

*This case test includes/understands only one modeling 2D planes in which one studies the influence of a load incremental.*

*The results obtained with Code\_Aster are compared with the calculations carried out using code ADINA.*

*Handbook de Validation*

in a bimetallic test-tube CT***

***Summary:***

***This test results from the validation independent of version 3 in breaking process.***

***It is about a two-dimensional test in statics (plane deformations) which relates to the calculation of a  
parallel crack***

***with the interface between two materials, for a noncommonplace geometry in limited field.***

***The structure has an elastoplastic behavior of Von Mises with isotropic work hardening.***

***The objective of this case test is the study of the sensitivity of G to the choice of the crowns.***

***It includes/understands two plane modelings 2D in which one studies the influence of an incremental***

***displacement***

***imposed. The first modeling uses linear elements, the other of the quadratic elements.***

## ***Properties of materials***

### ***Material n° 1: austenitic steel***

***Elastoplastic of von Mises type to isotropic work hardening***

***Young modulus  $E1 = 2.105 \text{ MPa}$ , Poisson's ratio  $1 = 0,3$***

***Yield stress  $y1 = 310 \text{ MPa}$***

***Uniaxial traction diagram:***

***(MPa)***

***0 310 600 700***

***(%)***

***0 0,155 40 100***

### ***Material n° 2: ferritic steel***

***Elastoplastic of von Mises type to isotropic work hardening***

***Young modulus  $E2 = 2.105 \text{ MPa}$ , Poisson's ratio  $2 = 0,3$***

***Yield stress  $y2 = 442 \text{ MPa}$***

***(MPa)***

***0 442 600 650***

***(%)***

***0 0,221 40 100***

### ***Material n° 3: quasi indeformable pins***

***Isotropic linear rubber band***

***Young modulus  $E3 = 6 \text{ 1010 MPa}$ , Poisson's ratio  $3 = 0,3$***

## ***1.3***

### ***Boundary conditions and loading***

***Being given the dissymmetry of materials, the totality of the test-tube is modelled.***

***Blockings:***

***$UX = UY = 0$***

***at the point B (center of the lower pin)***

***$UX = 0$***

***at point A (center of the higher pin)***

***Loading by imposed displacement:***

***0 UY 1 mm at point A, by equal increments of 0,02 mm***

***The loading is thus monotonous growing.***

### **Results of modeling A**

*The rate of refund of energy  $G$  is calculated by the method THETA for the 5 following crowns:*

· *Couronne 0:  $R_{inf} = 0,02 \text{ mm}$   $R_{sup} = 0,18 \text{ mm}$*

- *Couronne 1:  $R_{inf} = 0,2 \text{ mm}$   $R_{sup} = 1 \text{ mm}$*
- *Couronne 2:  $R_{inf} = 1 \text{ mm}$   $R_{sup} = 2 \text{ mm}$*
- *Couronne 3:  $R_{inf} = 2 \text{ mm}$   $R_{sup} = 3 \text{ mm}$*
- *Couronne 4:  $R_{inf} = 3 \text{ mm}$   $R_{sup} = 5 \text{ mm}$*

## **4.2 Remarks**

*The calculation of reference (Castem 2000) and Aster calculation use the same grid strictly.*

*The absolute value of the variation on the calculation of G for crowns 0 and 1 grows according to displacement to reach a value from approximately 5%.*

*For the other crowns, the variation decreases to reach a quasi null value.*

*Stability on crowns 2, 3 and 4 is very good, the difference between crowns is always lower than 1%.*

*Summary of the results*

*It should initially be announced that the reference solution is not an exact solution and that it does not apply, in general, in the case of the Bi-materials. Moreover it is based on one calculation of the linear elements. It is however exploitable for this study because the crack is not located at the interface of two materials.*

*Modeling A (degree 1) gives results in conformity with those of the reference.*

*Modeling B (degree 2) revealed a variation from approximately 8% on the value of G.*

*One can notice that the crowns far away from the crack provide more precise results and more stable than those close to the bottom of crack. The low-size crowns give results worse than those whose rays are important. Consequently, it seems judicious to use large-sized crowns for a modeling 2D.*

### **3 Modeling With**

#### **3.1 Characteristics of modeling**

*A modeling testing the functionalities of contact node-meshs (CONTACT) without friction treaty with the method of the active constraints was implemented. Taking into account the symmetry of problem, it includes/understands a quarter of the ring as well as the grid of an indeformable plate.*

#### **Boundary condition:**

*Conditions of symmetry: the nodes of group LAB located in the  $X=0$  plan are blocked according to direction  $X$  ( $DX=0$ ),  
the nodes of group LCD located in the  $Y=0$  plan are blocked according to direction  $Y$  ( $DY=0$ ),  
all the nodes of the group of mesh "Plate" are blocked according to direction  $X$  ( $DX=0$ )  
To avoid the rigid movements of body, nodes A and P1 have same vertical displacement.*

#### **Loadings:**

*Imposed displacement following  $Y$  on all the nodes of the plate:  $DY$  varies from 0 to 2,225 cm. (the value of 4,45 cm is the vertical bringing together of the two symmetrical plates).*

#### **Note:**

*The grid was carried out in cm.*

## **8.2 Remarks**

*The results are very close with those to modelings A and B.*

## **9** **Summary of the results**

*Whatever the type of modeling of the zone of contact, the results obtained are satisfactory. The variations observed on the force of reaction are weak. But the values of reference are very approximate because they are extracted from a curve paper.*

*The grid of the code computer taken in reference and that used by Aster are different. Moreover, it is not not explained in the reference how is extracted the normal pressure from contact. Thus, it does not have summer carried out of tests of reference on this pressure. However tests of not-regression are carried out on the contact pressure (SIYY to the node in contact). Pace of this pressure and the zone of contact are identical between the two computer codes.*

## 9 Summary of the results

*Whatever the type of modeling of the zone of contact, the results obtained are satisfactory.*  
*The variations observed on the force of reaction are weak. But the values of reference are very approximate because they are extracted from a curve paper.*

*The grid of the code computer taken in reference and that used by Aster are different. Moreover, it is not explained in the reference how is extracted the normal pressure from contact. Thus, it does not have summer carried out of tests of reference on this pressure. However tests of not-regression are*

*carried out on the contact pressure (SIYY to the node in contact). Pace of this pressure and the zone of contact are identical between the two computer codes.*

**Document: V6.04.102**

**SSNV102 - Tensile test shearing**

**with the model of S. TAHERI**

**Summary:**

The problem is quasi-static nonlinear in mechanics of the structures.

One analyzes the response of an element of volume to a loading in traction-shearing, carried out in such way

that that imposes a uniform state of stress-strain in the element.

There are 2 modelings: one in voluminal 3D and another in plane constraints 2D.

One validates by this test the numerical integration of the elastoplastic model of behavior of Said Taheri.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

One numerically integrates the following system between  $T = 0$  and  $T = 1$ .

(Nonlinear ordinary Differential connection of 6 equations to 6 unknown factors solved using

library NAG by a “Backward difference method”)

-

$$p = O$$

-

**4.2 Remarks**

The limitation with 10 of the maximum number of local iterations is very sufficient for a method of NEWTON exact in this case.

The reduction in the tolerance on total convergence in displacement does not bring profit significant in precision.

The number of increments of load (8) led to a satisfactory precision of the result.

model of Rousselier***

***Summary:***

*It is about a nonlinear quasi-static problem in mechanics of the structures.*

*One analyzes the response of an element of volume to a loading in traction-shearing, carried out of such way that that imposes a uniform state of stress-strain.*

*The case test includes/understands 1 modeling: in 3D.*

*It validates the numerical integration of the elastoplastic model of behavior with damage of G. Rousselier.*

## 2.2

### **Results of reference**

One imposes  $(T) = ()$   
 $0 + T$  with  $O = O = 150.MPa$ .

One obtains  $()$   
 $0 = 1.73138$  and  $()$   
 $1 = 2.73138$ .

The system  $(S)$  is then solved numerically by a “Backward difference formulated” using scientific library NAG on CRAY. Result of reference =  $(,)$  to the nodes with  $T = 1$ .

### ***4.2 Remarks***

*One could expect a better correlation, but it should be stressed that library NAG uses the function  $R(p)$  in algebraic form, whereas Code\_Aster uses it in the form of a curve data point by point.*

*Moreover, it seems that the integration of the rate of the function threshold poses problems with NAG, whatever*

*that is to say precision required in addition (the value of the threshold  $F$  being appreciably different from 0 in end*

of integration). However, one can note the constancy of this correlation throughout integration  
(T [  
0 ]  
1  
, ).

**SSNV104 - Contact of two phères**

**Summary:**

Calculation consists in crushing two quarters of spheres one on the other to test the algorithm of unilateral contact

in statics. The solution is compared with the analytical result of Hertz. This functionality returns within the framework

mechanics of the structures having a nonlinear behavior.

Three axisymmetric modelings suggested differ by the type of finite elements used (modeling AXIS, meshes TRIA3, QUAD4 and QUAD8).

### **Summary of the results**

The comparison of each of 3 modelings to the analytical reference (limited to the point G) is satisfactory for modeling A, less for modelings B and C.

The comparison of 3 modelings between them shows that:

- the deformations are superposable,
- the stress fields have marked enough local differences, in particular in zones Z1 and Z2. The phase of independent validation should make it possible to include/understand why.

In the command files, one ensures oneself of the not-degradation of the results by testing them displacements in two nodes of the edge, H and I. These nodes occupying of the positions slightly different according to modelings', one should not seek to compare the values of the cases A, B, C.

***SSNV112 - Hollow roll into incompressible  
(great deformations)***

***Summary:***

***This test makes it possible to validate the quasi-incompressible elements in great deformations, in statics for one three-dimensional, axisymmetric or two-dimensional problem (plane deformations). A cylinder is considered hollow subjected to an internal radial displacement. The material has a Poisson's ratio equal to 0.4999 and one use the quasi-incompressible elements (modeling INCO) with the deformations of SIMO\_MIEHE. Four modelings are carried out for this problem. Modelings A and B make it possible to test quasi-incompressible modeling 3D (3D\_INCO), on the one hand with HEXA20 (A) and on the other hand with TETRA10 (B). Modelings C and D are studies 2D being based on mixed grids QUAD8 and TRIA6. Modeling C is the study in plane deformations (D\_PLAN\_INCO), modeling D is a study axisymmetric (AXIS\_INCO).***

*This test is similar to the test SSLV130, which tests the quasi-incompressible elements under the assumption of small deformations.*

*The numerical results are satisfactory for all modelings.*

**4.5 Remarks**

*The results obtained are completely correct since the constraints are obtained with one precision lower than 3% even 0.5% at the point F. the variation is a little more important here than for HEXA20, but can be explained by the fact why the loading is imposed here in manner a little less specify since displacement U at point A, is defined only with one accuracy of 0.158% against 0.077% (evening factor 2, that one finds on the constraints).*

***Handbook of Validation***

***V6.04 booklet: Nonlinear statics of the voluminal structures***

***V6.04.115 document***

***SSNV115 - Iron corrugated in behavior  
nonlinear***

***Summary:***

***This problem validates the elastoplastic law of behavior with criterion of Von Misès with linear work hardening isotropic for modelings of plates [R3.07.03] and voluminal hulls [R3.07.04] where effects of membrane and of inflection are also important.***

***The geometry of the model respects 3 constraints:***

- .  
the thickness is low to respect the assumption of the thin hulls,***
- .  
the problem must be in plane deformation according to OZ,***
- .  
the curve according to OY is selected so that the “inflection” and the “membrane” are both significant.***

***There is no analytical solution. Modeling A (2D D\_PLAN) is used as reference. The test does not have physical significance and the values of displacements obtained are very important compared to***

*dimensions of the initial structure. This test is thus rather a test of not-regression and comparison inter-modelings.*

*The results (in displacement) differ from 2 to 3% between modelings plates and the reference 2D. This variation is reduced to 0.5% between modelings voluminal hulls and the reference 2D.*

## **1.3**

### **Boundary conditions and loadings**

.

*on AB: embedding:  $DX = DY = DZ = DRX = DRY = DRZ = 0$ ,*

.

*on all the hull: deformation planes according to  $OZ \Rightarrow DZ = DRX = DRY = 0$ ,*

.

*on CD: linear effort (by unit of length  $OZ$ ) according to  $OX$  given by:  $f_x = 50 \text{ N/mm}$  It is equivalent with a pressure of  $p_x = f_x / h = 100 \text{ MPa}$  being exerted on the side  $CD$ ,*

.

*the loading is applied gradually to the structure. The way of loading is cut out in 10 equal increments.*

$f_x$  5.

0.

1.  $T$

## **2**

### **Reference solution**

#### **2.1**

#### **Method of calculation used for the reference solution**

*Modeling A (2D  $D\_PLAN$ ) is used as reference for modelings of hull.*

## 2.2

### ***Results of reference***

*Displacements according to OX and OY of item X in Misters.*

## 2.3

### ***Uncertainty on the solution***

*The experiment shows that if one doubles the number of elements in the two directions, the result varies of less than 2%.*

*The selected criteria of convergence must also make it possible to reach the precision estimated for this calculation 2D: (2 or 3%).*

### **16 Summary of the results**

*One notices the good adequacy of the reference solution Aster 2D deformation planes with results obtained by modelings in voluminal hulls. The variation on displacements at the point of maximum arrow on the initial geometry is indeed lower than 1%. The variation with modeling in linear hull is of about a 1.5% on the estimate of the maximum arrow of sheet. This variation becomes more important for modelings in elements of plates which do not take into account curve of corrugated sheet. The relative error on the estimate of the maximum arrow does not seem to want to go down in lower part from 3%, and this same by increasing the number of layers for to improve integration of plasticity in the thickness of the element. It is noticed for this reason that one increase in the number of layers in the thickness makes it possible to improve the estimate of displacement*

*DX at the point where the arrow is maximum without to improve the estimate of the latter, and it,*

*for the whole of the studied models. The difference in quality of results between the various models undoubtedly comes from the taking into account of the curve of corrugated sheet.*

## 2

### **Reference solution**

#### 2.1

##### **Method of calculation used for the reference solution**

One uses to establish the reference solution the software SIDOLO which allows simulation and identification of laws of behavior.

The equations of the model are written by the user in FORTRAN in the form of a system of equations first order differentials, solved by a method of Runge Kutta of order 4 with adaptive step.

#### 2.2

##### **Results of reference**

$\epsilon_x, \epsilon_y, \epsilon_z, \epsilon_{xy}, \epsilon_{xz}, \epsilon_{yz}, p, R, Q$  at the moment  $P$  ( $T = 10$  S) or  $\epsilon_1$  et  $\epsilon_2$  are the variables of kinematic work hardening,  $p$  cumulated plastic deformation,  $R(p, Q)$  the variable of work hardening isotropic and the internal variable allowing the taking into account of the memory of work hardening.

#### 2.3

##### **Uncertainty on the solution**

Uncertainty of SIDOLO.

#### 2.4 References

##### **bibliographical**

### **Summary of the results**

The equations of the model being strongly nonlinear, it is necessary to use increments of small times to obtain a precise solution.

On this test presenting a geometry and boundary conditions simple, the recutting of the step of time at the local level makes it possible to improve the precision of the results without increasing the time too much of calculation.

**SSNV121 - Rotation and traction hyper-rubber band of a bar**

**Summary:**

This test of quasi-static mechanics consists in making turn of 90° a parallelepipedic bar, with to subject to an important traction for finally letting it return in a discharged state. One validates thus kinematics of the great deformations hyper-rubber bands (order STAT\_NON\_LINE [U4.32.01], key word

COMP\_ELAS), and thus in particular great rotations, for a relation of elastic behavior linear.

The bar is modelled by a voluminal element (HEXA8, modeling A) or plan (QUAD4, assumption plane deformations, modeling B).

The results obtained by Code\_Aster do not differ from the theoretical solution.

**Reference solution****2.1****Method of calculation used for the reference solution**

It is about a plane problem. One can seek the solution in the form of a rigid rotation and one lengthening of a factor in direction  $Y$ .

-  $X$  -  $Y$  $\mathbf{U}(X, Y, Z) =$  $(1 + \frac{1}{2} \frac{Y^2}{L^2}) X - Y$ 

0

The gradient of the transformation and the deformation of Green-Lagrange are then:

0

-1

0

 $E$  0

0

 $( + 2)$  $\mathbf{F}$ 

=

1 +

0

0  $\mathbf{E}$ 

= 0 0

0

with  $E =$ 

2

0

0

1

0 0 0

The relation of behavior leads then to a tensor of Lagrangian constraints diagonal:

(1)  $E$  $S$ 

=

 $xx$ (1+) (1 - 2)  $E$  $E$  $S$ =  $S$ 

=

 $yy$  $zz$ (1+) (1 - 2)  $E$ 

The boundary condition of the equilibrium equation then enables us to determine the value of lengthening:

(1-)

+1 +

= (

2

**FS)**

= (1+ )

 $E$ 

(

)(

)

 $T$  $S$ 

(

=

1 + )(1- 2 )

 $T$  $yx$  $xx$ 

2

The constraint of Cauchy is given by:

$$S_{yy}$$

$$1$$

$$xx$$

$$=$$

$$zz$$

$$=$$

$$=$$

$$\mathbf{F} \mathbf{S} \mathbf{F}^T$$

$$1+$$

$$\text{Det } \mathbf{F}$$

$$yy$$

$$= (1+ )$$

$$S_{xx}$$

Lastly, the force exerted on the faces:

$$\cdot [2,4]: F$$

$$=$$

$$=$$

$$y$$

$$yy$$

$$[$$

$$S_{2,4}]$$

$$yy \text{ } So [2,4]$$

$$\cdot [4,3]: F$$

$$=$$

$$= 1+$$

$$X$$

$$xx$$

$$[$$

$$S_{4,}] \text{ } 3$$

$$xx ($$

$$) \text{ } So [4,] \text{ } 3$$

$$\cdot [1,2,3,4]: F$$

$$=$$

$$= 1+$$

$$Z$$

$$zz$$

[  
 $S_{1,2,3,4}$   
 $zz$  (  
)  $So_{1,2,3,4}$   
where  $S$  [  
 $O$ ]

initial surfaces of the faces represent.

### Results of reference

One adopts like results of reference displacements, the constraint of Cauchy and the force exerted on the faces [2,4] and [4,3].

**At time  $T = 2 \text{ S}$ :**

One seeks  $T$  such as lengthening  
= 01.

$\Rightarrow T = 31\,096.154 \text{ MPa}$ .

The constraint of Cauchy is then:

=

=

$xx$

$zz$

11 013.986 MPa

=

$yy$

31 096.154 MPa

The exerted forces are:

$F$

= 12.115.385

.

×

$X$

$So [4,] NR$

3

$F$

= 31 096.154 ×

$y$

$So [2,4] NR$

$F$

= 12 115.385 ×

$Z$

$So [, 12, 34] NR$

**At time T = 3 S:**

The bar returned in its initial state:

= 0

= 0

$F =$

0

### **Summary of the results**

It appears at the end of this test that the numerical solution coincides remarkably with the solution analytical. It will be noticed however that the strong not linearity due to great rotations requires a relatively fine discretization in time, without being penalizing on the precision since, contrary to an incremental law of behavior, the errors do not cumulate a step of time on the other.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

It is about a plane problem. One can seek the solution in the form of a rigid rotation followed of one dilation of a factor  $has$  in a direction and  $B$  in the other:

$X$

-  $Y$

$B$  (-  $Y$ )

-  $X$  -  $bY$

rotation

traction

$Y$

$X$

$X$  *has*

that is to say  $U = AX$

-  $Y$

$Z$

$Z$

$Z$

0

The gradient of the transformation and the deformation of Green-Lagrange are then:

2

0

-  $B$

0

$E$

0

has -

0

1

X

ex =

**F**

=

has

0

0 **E**

= 0 ey

0

2

where

2

B - 1

0 0

1

0

0

0

E y =

2

The relation of behavior leads to a tensor of Lagrangian constraints diagonal (with and  $\mu$  coefficients of Lamé):

S

= + 2 $\mu$

+

xx

(

) E

E

$$X$$
$$y$$
$$E$$
$$= 1+ 1 - 2$$
$$S$$
$$= E$$
$$+ + 2\mu$$

$$yy$$
$$X$$
$$($$
$$)$$
$$($$
$$)($$
$$)$$
$$E y$$

where

$$E$$
$$\mu = (21+)$$
$$S$$
$$= E$$
$$+ E$$

$$zz$$
$$X$$
$$y$$

One deduces the tensor from it from the constraints of Cauchy, him so diagonal:

$$B$$

*has*

$$=$$
$$=$$
$$= 1$$
$$X$$
$$S y$$
$$y$$
$$S X$$
$$Z$$
$$S_z$$

*has*

$$B$$

*B has*

Finally the boundary conditions are written:

$$= 0 \text{ (edge libr)}$$
$$E$$

= -

$X$

(traction)

$y$

$p$

One can moreover calculate the efforts exerted on the faces:

[1, 3]

$F = - B S$

$y$

$y$

$O [1, 3]$

[3, 4]

$F = 0$

$X$

[

-  $ab S$

on the lower side of the face

$Z$

$O 1, 2, 3, 4$

1, 2, 3, 4]

[

]

$F =$

$Z$

$Z ab So$

[1, 2, 3, 4] on the higher side of the face

where  $So []$  represent initial surfaces of the faces.

## 2.2

### Results of reference

One adopts like results of reference displacements, the deformations of Grenn-Lagrange, them constraints of Cauchy and forces exerted on the faces [1, 3], [3, 4] and [1, 2, 3, 4] in end of loading ( $T = 2 \text{ S}$ ).

One seeks  $p$  such as dilation  $has = 1,1$

$\Rightarrow p = 26610.3 \text{ MPa}$ .

Dilation  $B$  and displacements are then:

$B = 0.9539 \quad E = 0.105 \quad E = -$

$X$

$y$

0.045

The constraints of Cauchy vallent:

$= 0$

$= 26610.3 \text{ MPa}$

$=$

### **Summary of the results**

It appears at the end of this test that the numerical solution coincides remarkably with the solution analytical. It will be noticed however that the strong not linearity due to great rotations requires a relatively fine discretization in time, without being penalizing on the precision since, contrary to an incremental relation of behavior, the errors do not cumulate a step time on the other.

**SSNV124 - Analyze regularized limit.**

**Law of Norton-Hoff**

**Summary**

This test makes it possible to validate the operators used analyzes regularized limit of it. One calculates the load limits by

a kinematic approach regularized by the method of Norton-Hoff-Friaâ.

One considers a rectangular plate (modeling A) or a cube (modeling B) or a cylinder axisymmetric (modeling C). The constitutive material checks the criterion of von Mises and the structure is subjected

with loadings on the edges. Calculation makes it possible to obtain the limiting load in the direction of the loading.

The structure is modelled by incompressible elements and the loading is standardized.

The resolution by the regularized method of Norton-Hoff-Friaâ is carried out in order

STAT\_NON\_LINE

[U4.32.01]. A postprocessing in order POST\_ELEM [U4.61.04] makes it possible to obtain the value of a terminal

higher of the limiting load, .ainsi qu' an estimate.

The reference solution is analytical and the results are in perfect agreement with the values of reference.

### Reference solution

#### 2.1

#### Method of calculation used for the reference solution

One considers a rectangular plate (modeling A) or a cube (modeling B) or a cylinder axisymmetric (modeling C). The constitutive material checks the criterion of von Mises, with for threshold  $Y$ .

The structure is subjected to pressures on the edges horizontal -  $F$  and vertical -  $(1 -) F$  with

0.5 (= 1.en 2D, = 0.8 in 3D). In plane 2D, one considers two ways of making: on the one hand in amplifying the two pressures together, in addition while amplifying that horizontal pressure, and in leaving the constant vertical. Into axisymmetric, the solid is subjected to the internal pressure only -  $F$ . One obtains the exact limiting load and that by the method of regularization [R7.07.01] in this direction of loading, for the criterion of von Mises, with threshold  $Y$ .

### **Summary of the results**

The numerical results are in perfect agreement with the values of reference. In the case axisymmetric, the light differences are explained by the fact why displacement is into  $1/R$  in analytical solution, which is not included/understood in the base of the selected finite elements.

## **4.2 Remarks**

*The moment 6s corresponds to a loading where there was not plasticization yet.*

*One uses 11 increments of time in Aster, and the step of time is redécoupé in manner adaptive on the level of the local integration of the equations of the model (explicit cf Integration [R5.03.14]).*

*SiDoLo uses several hundreds of step of times, calculated automatically.*

## **6.2 Remarks**

***Modeling B uses the key word factor POLY\_CFC\_FO with a constant evolution of parameters.***

***The criterion of total convergence (RESI\_GLOB\_RELA) is higher of a factor 10 compared to modeling A (saving of time of calculation but loss of a factor approximately 10 on the results of constraint); it is noted that the answers in deformation remain of an order of magnitude close to those modeling A. Moreover, with an accuracy of 102 on balance one has an error of 6% on deformation yz.***

***V6.04 booklet: Nonlinear statics of the voluminal structures***

***Document: V6.04.127***

***SSNV127 - Roll in a boring with contact  
and friction***

***Summary:***

***This problem corresponds to a quasi-static analysis of a problem of mechanics with contact and friction.***

***A cylinder is compressed in a cylindrical boring of slightly higher diameter by a force concentrated applied to its axis.***

*This test, named “problem of Klang”, is rather largely used in the literature to validate modelings of contact with friction and was in particular used by P. Alart and A. Curnier [bib1] to validate their finite elements of contact and friction.*

*Five modelings 2D are proposed (A, B, C and D with linear elements and E with elements quadratic):*

*Modeling A tests the “LAGRANGIAN” algorithm of the method with master-slave pairing.*

*Modeling B tests the “LAGRANGIAN” algorithm of the method with nodal pairing.*

*Modeling C tests the algorithm of the method “PENALIZATION” with master-slave pairing, penalization relates only to friction.*

*Modeling D tests the algorithm of the method “PENALIZATION” with master-slave pairing, penalization relates to the contact and friction.*

*Modeling E tests the “LAGRANGIAN” algorithm of the method with master-slave pairing.*

*Modelings F and H test the algorithm of the “CONTINUOUS” method with quadratic elements (SEG3) and linear (SEG2) of contact, respectively.*

*The results are compared with an analytical solution given by Klang [bib2].*

*Instead of reproducing this relatively complicated analytical solution we will use the values of pressures obtained from this one [bib1].*

## **11 Modeling**

**E**

### **11.1 Characteristics of modeling**

*The symmetry of the problem makes it possible to model of it only half (X 0).*

*30 finite elements SEG3 are laid out regularly on surface of contact. Because of curve of these elements, one uses the method of projection “QUADRATIC”.*

*The cylinder and circular volume surrounding boring are with a grid with elements QUA8 and TRIA6.*

## 8.3

**Titrate:****SSNV127 - Roll in a boring with contact and friction****Date:****04/05/06****Author (S):****Mr. KHAM, S. LAMARCHE, P. MASSIN, Key Mr. TORKHANI: V6.04.127-C Page: 18/18****17 Summary of the results**

*The results are of good quality if it is considered that they are compared with an analytical solution and*

*that the grids used are not particularly fine.*

*The best solutions are given by modelings E and F (algorithms Lagrangien and continuous, respectively) which uses quadratic elements with quadratic projection (without using this projection, the results are false). Then modelings A and H come which, like the preceding one, use the algorithms Lagrangien and continuous, respectively, with main pairing slave. If one uses nodal pairing (modeling B), the solution is good but it is necessary to underline that this technique of pairing is limited to the small slips. Finally modelings C come and D which use the algorithm of penalization and which give acceptable results. Let us note that convergence with these algorithms is much slower and difficult.*

*If one examines the extent of the surface of contact using the impression of the structure of data VALE\_CONT (see file of results), one notes that it is given very precisely (60°). In what relate to adherent surface, the algorithms return an acceptable value about 30° to place of 26.2° analytically.*

*.*

*by a complete embedding.*

*The frame, when it is of the same dimension than the plate, is blocked:*

*.*

*in the plan  $X = 40$  mm for displacements according to  $X$  (symmetry of the problem),*

*.*

*by an embedding of its lower face,*

*The plate is blocked:*

*.*

*in the plan  $X = 40$  mm for displacements according to  $X$  (symmetry of the problem),*

*.*

*according to  $Y$ , with the node located at the intersection of, the face symmetry plane of contact and plan*

*$Z = 0$  to prevent the movements of rigid body,*

*In 3D, to bring back itself to a problem 2D:*

•  
*displacement following Z is blocked for all the nodes,*

*The plate is subjected to two pressures distributed:*

•  
*a vertical acting under the face of the top:  $F = 5 \text{ daN/mm}^2$ ,*

•  
*horizontal acting under the face initially in  $X = 0$ ,  $F = 15 \text{ daN/mm}^2$ .*

## **2** *Reference solution*

### **2.1** *Method of calculation used for the reference solution*

*The reference solution comes from results obtained by an average on other computer codes [bib1].*

### **2.2** *Results of reference*

*Tangential displacements (according to X) at points A B C D E of the surface of contact.*

### **2.3 Reference** *bibliographical*

## ***39 Summary of the results***

***The results obtained on the whole of modelings of this case test are satisfactory, as well in 2D that in 3D. On points A, B, C and D, one obtains a relative error lower than 1% compared to results of the GRECO. On the other hand, for the point E, the relative error, about 2,5%, remains acceptable.***

***From a time point of view computing, one notes that the method by penalization is in general more rapid that Lagrangian method. One notes, on the other hand, an ease of use of the method Lagrangian (cf Doc. [R5.03.01]) compared to the penalized method, since convergence and quality of the results obtained by this last method are conditioned by the coefficient of***

*penalization which is automatically given in the Lagrangian method.*

*From a qualitative point of view:*

*.*  
*in 2D, one notes a positive effect on the results of the quadratic grid compared to linear grid (cf modelings A and B),*  
*.*  
*in 3D, one notes that calculations with quadratic grid does not improve the results.*  
*This is explained by the fact why one decreased by 50% the number of meshes compared to linear grid to have a number of nodes are equivalent.*

*As regards modeling L, inclined plate, one notes a good convergence and results satisfactory.*

*Lastly, for the method continues (modelings M, NR, P and Q), one obtains in 3D results with relative errors slightly more important than those obtained by the methods Lagrangian and penalized. These errors can come from the choice of the coefficients (cf the documentation of use orders AFFE\_CHAR\_MECA and AFFE\_CHAR\_MECA\_F for more information on these coefficients). In 2D, one notes a convergence slower than the methods Lagrangian and penalized. Lastly, the exclusion of the nodes rubbing in redundancy with the boundary conditions imposed (pivot no one) using SANS\_GROUP\_NO and VECT\_Y functions correctly in 2D (modeling Q) but increase the level of error in 3D (modeling R).*

## **2.4 Comments**

*It is noted that the results obtained without contact are very satisfactory for a modeling of type DKT. The error obtained for a modeling of the type COQUE\_3D can be explained by the catch in count effects of transverse shearing which should not be negligible for this plate relatively thick since the l/e report/ratio is worth 1/10.*

*Moreover, the effect of the size of the grid would be also to analyze by taking grids 100x100 with place of grid 16x16.*

**7**

**Summary of the results**

*One notes very good results in the presence of contact for two modelings.*

*Modeling A (DKT) has very satisfactory results compared to the analytical results (1% of error with or without contact). When one replaces a plate under pressure by two plates from which one comes to be stuck to the other, the multiplication of rigidity by two results in one division by two of the maximum arrow as well as constraint in the center of the plates.*

*Modeling B (COQUE\_3D) gives a behavior are equivalent to that met for modeling A in DKT when one replaces a plate under pressure by two plates in contact. One observes a division by two of the maximum arrow as well as constraint in the center of plates. Moreover, the value of the arrow obtained is rather satisfactory (~7% of error) compared to*

*analytical results. This difference can be explained by the taking into account of shearing transverse for the COQUE\_3D for a plate which is altogether relatively thick since  $l/e = 1/10$ .*

***Mixed work hardening***

## **Summary:**

*The purpose of this test is to validate elastoplastic behaviors VMIS\_ECMI\_TRAC and VMIS\_ECMI\_LINE, which combine an isotropic work hardening (linear or given by a traction diagram) and a work hardening linear kinematics.*

*The geometrical and mechanical data make it possible to be in uniaxial situation (uniform constraints, one only nonnull component). The reference solution is simple, analytical. This test allows simply to check that the integration of the model of behavior is correct.*

*3 modelings make it possible to check the uniaxiality of the constraints: 3D, AXIS, C\_PLAN.*

***SSNV135 - Triaxial compression test drained with model CJS***  
***(level 1)***

***Summary***

*This test makes it possible to validate level 1 of model CJS. It is about a triaxial compression test in drained condition. Three levels of containment are simulated: 100, 200, then 400 kPa.*

*By reason of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test.*

*The results obtained with model CJS1 are compared with the analytical solution.*

**:**

**V6.04.135-A Page:**

**3/8**

**2**

**Reference solution**

**2.1**

**Development of the analytical solution for CJS1**

**One has permanently:**

**= = 0**

**xx**

**yy**

**xx**

**where 0**

**you**

**xx = C represents the confining pressure.**

**Remain to determine zz.**

**Elastic phase:**

**By writing the elastic law simply, one a:**

**0 = 0 + + (+ 2 μ) +**

$\sigma_x$  $\sigma_x$  $\sigma_z$  $\sigma_x$  $\sigma_x$ 

$$= 0 + (+ 2 \mu) + 2$$

 $\sigma_z$  $\sigma_z$  $\sigma_z$  $\sigma_x$ 

where here and  $\mu$  is the coefficients of Lamé.

By eliminating  $\sigma_x$  between these two equations, one finds:

$$\mu (3 + 2 \mu)$$

$$= 0 +$$

 $($  $\sigma_z$  $\sigma_z$ 

$$+ \mu)$$

 $\sigma_z$ 

Plastic phase:

One a:

 $I$  $0$  $0$ 

you

$$I = \sigma_z + 2 \sigma_x \text{ where } \sigma_x = C \text{ represents the confining pressure.}$$

One deduces some for the components from the diverter S:

 $I$  $0$  $I$ 

$$S = 2$$

 $I$  $\sigma_z$ 

-  $\sigma_x$

*and S*  
*= 0 - I*  
*3 1*

*xx*  
*xx*  
*1*  
*3*  
  
*1*  
*3*  
*0*

*1*  
*0*  
*that is to say: S*  
*= 6 - I*  
*II*  
*xx*

*and det (S) = 2*  
*I -*

*3 1*  
*xx*  
  
*3 1*

*1/6*  
*Consequently: (*  
*H S) = (1 -)*

*In addition, when one reaches the criterion of the mechanism déviatoire: S*  
*(H) + R I*  
*II*  
*S*  
*m*  
*=*  
*1*  
*0*  
*from where the relation:*

**0**  
**6**  
**I**  
**xx**  
**I =**  
  
**2**  
**Rm**  
**-**  
**3**  
**(1 -) 1/6**

### ***SSNV136 - Triaxial compression test drained with model CJS (level 2)***

#### **Summary**

*This test makes it possible to validate level 2 of model CJS. It is about a triaxial compression test in drained condition.*

*calculations are carried out only on the solid part of the ground, without hydraulic coupling. The level of containment is of 100 kPa.*

*By reason of symmetry, one is interested only in the eighth of a sample 3D subjected to a triaxial compression test.*

*It is about a test of nonregression. Nevertheless, results obtained with Code\_Aster for model CJS2 are compared with those obtained with a private version of software FLAC 2D.*

## ***SSNV137 - Cable of prestressed in a beam concrete right-hand side***

### ***Summary***

***One considers a right concrete beam, of square section, crossed over his length by a cable of prestressed out of steel. In at-rest state, the cable is parallel to fibre average of the beam and excentré by report/ratio in the two principal plans. The beam and the cable are embed-free. The cable is put in traction at its loose lead, in order to prestress the beam in inflection-compression. Losses of tension along cable are neglected.***

***The goal of this case-test is to validate the method of calculation of the state of balance of a concrete structure prestressed, when this structure is modelled by elements 3D, associated the basic elements representing the cable of prestressing.***

***The functionalities particular to test are as follows:***

- .  
operator DEFI\_CABLE\_BP: determination of the relations kinematics between the DDL of the nodes of one cable and the DDL of the nodes “close” to a concrete structure modelled by elements 3D;***
- .  
operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance.***

***The results obtained are validated by comparison with an analytical solution of reference.

**Problem of reference**

**1.1 Geometry**

**The concrete beam is right, of square section.**

**Its dimensions are  $L \times has \times has = 3\text{ m} \times 0,4\text{ m} \times 0,4\text{ Mr}$ .**

**The cable crosses the beam parallel with average fibre and it is excentré compared to the two plans principal. The eccentricities according to directions y and Z are worth respectively  $e_y = -0,12\text{ m}$  and  $e_z = -0,16\text{ Mr}$ .**

**The surface of the cross-section of the cable is worth  $Its = 2,5.103\text{ m}^2$ .**

***Properties of materials***

***Material concrete constituting the beam: Young modulus  $E_b = 4,5.10^{10}$  Pa***

***Material steel constituting the cable: Young modulus  $E_a = 1,85.10^{11}$  Pa***

***The Poisson's ratio is taken equal to 0 for two materials. One thus cancels the effects of Poisson in directions y and Z.***

***Losses of tension in the cable being neglected, the various parameters being used for their estimate are fixed at 0.***

### **1.3**

#### **Boundary conditions and loadings**

*The nodes of the beam located on the face  $x=0$  are blocked in translation according to the three directions.*

*Among these nodes are the “neighbors” of the left node end of the cable, which is thus blocked in translation by the relations kinematics. One thus should not impose conditions on additional limits in this node, which would be redundant with the relations kinematics and would make impossible the resolution in displacements (singular matrix).*

*One applies to the node right end of the cable a normal effort of traction ( $F_0; 0; 0$ ), with  $F_0 = 106$  NR.*

#### **Reference solution**

*The analytical solution of reference is determined by the theory of the beams. One is considered embed-free beam. The geometrical characteristics are those defined in paragraph [§2.1]. One applies at the loose lead a normal effort of compression ( $F; 0; 0$ ) and a bending moment ( $0; e_z. F; e_y. F$ ).*

*The solution of this problem is as follows:*

*Tensor of the constraints:*

***3.1***

***Characteristics of modeling***

***The concrete beam is represented by 60 elements MECA\_HEXA20, supported per as many meshes hexahedrons with 20 nodes. The figure below gives a simplified representation of the grid of beam.***

*A material concrete is affected with the elements, for which behaviors ELAS are defined (Young modulus  $E_b = 4,5.10^{10}$  Pa) and BPEL\_BETON: parameters characteristic of this relation are fixed at 0 but one neglects the losses of tension along the cable of prestressing.*

*The DDL DX, DY, and DZ of the nodes of the face  $x=0$  are blocked.*

*The cable is represented by 30 elements MECA\_BARRE, supported per as many meshes segments to 2 nodes. The ends left and right-hand side are respectively nodes NC000001 and NC000031.*

*A surface of cross-section  $I_{ts} = 2,5.10^3$  m<sup>2</sup> is assigned to the elements, as well as a material steel for which are defined behaviors ELAS (Young modulus  $E_a = 1,85.10^{11}$  Pa) and BPEL\_ACIER: parameters characteristic of this relation are fixed at 0 (neglected losses of tension), except stress ultimate elastic for which a zero value is illicit ( $f_{prg} = 1,77.10^9$  Pa).*

*To avoid any redundancy with the relations kinematics, no blocking is forced on the node NC000001 (cf notices paragraph [§2.3]).*

*The  $F_0$  tension = 106 NR is applied to node NC000031. This value of tension is coherent with values of section and yield stress, for a cable of prestressed of strand type.*

*The calculation of the state of balance of the beam unit and cable is carried out in only one step, its behavior being elastic. One carries out then a complementary calculation allowing to determine constraints with the nodes of the elements of the beam.*

#### ***Stages of calculation and functionalities tested***

***The principal stages of calculation correspond to the functionalities which one wishes to validate:***

**.**

***operator DEFI\_MATERIAU: definition of the relations of behavior BPEL\_BETON and BPEL\_ACIER, in the particular case where losses of tension along the cable of prestressed are neglected (default values of the parameters);***

**.**

***operator DEFI\_CABLE\_BP: determination of a constant profile of tension along the cable of prestressing, losses being neglected  
; calculation of the coefficients of the relations  
kinematics between the DDL of the nodes of the cable and the DDL of the nodes “close” to beam out of concrete, in the case of a beam modelled by elements 3D;***

**.**

***operator AFFE\_CHAR\_MECA: definition of a loading of the type RELA\_CINE\_BP;***

**.**

***operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance by holding account  
loading of the type RELA\_CINE\_BP, in the case of a beam modelled by  
elements 3D.***

***One uses finally operator CALC\_ELEM option SIGM\_ELNO\_DEPL in order to calculate the constraints with  
nodes of the elements of the beam.***

**5**

**Summary of the results**

***The computed values correspond indeed to those theoretically awaited. One obtains well a state of inflection-compression for the concrete beam.***

***The more important variations observed in certain nodes closer to the loose lead can to be explained by the more or less good adequacy of a modeling 3D for a structure of the type beam. Thus the grid remains enough coarse not to increase the cost of calculation. One recalls finally that the reference solution is established under the assumptions of the theory of the beams.***

**Reference solution**

2.1

**Method of calculation used for the reference solution**

*With a kinematics of beam and a model in resulting efforts, curve (in great rotations) cantilever subjected to the bending moment  $M = mb$  is, with the preceding numerical data:*

$D$

$mb$

$T$

$=$

$=$

$dx$

*I.E.(internal excitation)*

$L$

$y$

*It is the solution of Euler.*

2.2

**Results of reference**

$L$

$R =$

$R \sin$

$R 1$

$(-\cos)$   
 $L$

According to the solution of Euler, the deformation is an arc of circle. With section 2  
 $P$  3  
 $P(X = L)$ , rotation  
 is worth:

$$(X = L) = T.$$

In the absence of normal effort, average surface remains inextensible and the radius of curvature is  
 given  
 by:

$$D - I$$

$$L$$

$$R =$$

$$=$$

$$dx$$

$$T$$

Horizontal displacement is then

$$\sin$$

$$U =$$

$$T$$

$$R \sin - L = L ($$

$$- )$$

$$I$$

$$T$$

and vertical displacement is

$$L$$

$$v = R I$$

$$(-\cos) =$$

$$I$$

$$(-\cos t)$$

$$T$$

### **Summary of the results**

*One notices difficulties of convergence which disappear by multiplying the thickness by 3 or 4.*

*It is necessary to increase the value of the COEF\_RIGI\_DRZ which allots a rigidity around normal of the elements of hull which is worth by defect 105 (the smallest rigidity of inflection around directions in the plan of the hull) in order to be able to increase the value of the swing angle that one can reach. Values of this coefficient up to 103 remain licit.*

*During the iterations of Newton, deformations of membrane appear and are cancelled with convergence.*

*Speeds of convergence of the algorithms of NEWTON are comparable for modelings POU\_D\_T\_GD and COQUE\_3D.*

***SSNV140 - Embedded cylindrical panel***

***Summary:***

*One presents in this test a quasi static calculation of embedded elastic cylindrical panel subjected to one surface force data either in the total reference mark, or in the local reference mark. This force is constant in first case and following in the second case. Nonlinear modeling COQUE\_3D thus is tested geometrical by using the algorithm of update of great rotations 3D GREEN\_GR of STAT\_NON\_LINE, as well as the treatment of the following pressures for modeling COQUE\_3D. The reference solution which is numerical is obtained with software the SAMCEF software.*

## **9** **Summary of the results**

*H*  
The facts of the case correspond to a thin hull  
= 0.625%  
.  
what is severe for  
*L*  
the finite element triangle MEC3TR7H (not presented here but presenting a case of blocking at shearing transverse). The deformation is primarily membranous and rotations remain moderate.  
  
The reference solution obtained by software the SAMCEF software is numerical and its grid twice more end than that used here. Its model finite elements rests on an approach in resulting efforts with a rotational formulation [bib3]. The approach chosen in Code\_Aster is 3D forced plane with a formulation Lagrangian total [R3.07.04]. The quality of the results obtained is good. The variation compared to this solution is lower than 0.5% for the vertical displacement of the central point.

***SSNV142 - Clean creep test: Granger model***

***Summary:***

***This case-test of nonlinear quasi-static mechanics relates to a creep test on a cylinder axisymmetric. It aims to validate the relation of behavior of “Granger”, relation of behavior which one introduced into Code\_Aster to model the clean creep of the concretes. This model is a linear viscoelastic model (grouping of rheological models of Kelvin in series) which allows to take into account the history of the constraint, the temperature and the hygroscopy.***

***In this test, the constraint, the temperature and the hygrometrical state are constant.***

***The cylinder is modelled by four elements quadrangles with 8 nodes.***

***The results obtained by Code\_Aster are compared with the analytical solution of reference.***

### ***Reference solution***

## **2.1**

### ***Method of calculation used for the reference solution***

*Being given the nature of the requests, the solution (forced, deformations) is homogeneous.*

*0*  
*0*  
*0*

*That is to say the loading: 0 () 0*

*D T*

*0*  
*0*  
*0*

*The clean model of creep of Granger is such as the viscoelastic deformation corresponding to the case of a constant loading 0 applied to the moment t0 is worth: (cf [R7.01.01])*

*K =8*  
*T - T*  
*fl (T) =*  
*0*  
*0 Jk (1 - exp-*  
*K =1*  
*S*

*The model also depends on the temperature and the hygroscoy in the following way:*

*K*  
*-*  
*=8*  
*248*  
*T - T*  
*fl*  
*T*  
*(T) =*  
*0*  
*0 H*  
*Jk (1 - exp-*

*45*

)  
 $K=1$   
 $S$

*but in this test the fields of temperature and hygroscoPy are selected constant and such as  $H$  and  $T - 248$  are worth 1 respectively.*  
45

*When the constraint evolves/moves with time then:*

$K=8 T$   
 $T -$

$D$   
 $fl(T) = Jk(1 - exp-)$

$K=1$   
 $S$   
 $D$   
 $=0$

*one thus has for the case present:*

$T$   
 $2=t$   
 $K=$   
 $l$   
 $fl$   
 $T -$

$l$   
 $yy =$   
 $Jk(1 - exp-) D$   
 $K=1$   
 $S$   
 $T$   
 $T =$   
 $l$   
 $0$

*the loading remaining constant beyond  $T1$ .*

***Handbook of Validation***  
***V6.04 booklet: Nonlinear statics of the voluminal structures***  
***V6.04.143 document***

***SSNV143 - Biaxial traction with the law of  
behavior BETON\_DOUBLE\_DP***

***Summary:***

***This case of validation is intended to check the model of behavior 3D BETON\_DOUBLE\_DP  
formulated in  
tally of thermoplasticity, for the description of the nonlinear behavior of the concrete, in traction, and  
in  
compression, with the taking into account of the irreversible variations of the thermal characteristics  
and  
mechanics of the concrete, particularly sensitive at high temperature.***

*The description of cracking is treated within the framework of plasticity, using an energy equivalence, by identifying the density of energy of cracking in mode I, with the plastic work of a homogeneous medium equivalent, where the plastic deformation is uniformly distributed, in an “elementary” zone. This approach preserve the continuity of the formulation of the model, on the whole of its behavior, and contributes to avoid possible numerical difficulties during the change of state of material. Pathological sensitivity of the numerical solution to the space discretization (grid), generated by the introduction of a softening behavior of the concrete in traction and compression, is partially solved by introducing an energy of cracking or rupture, dependent a characteristic length  $l_c$ , related to cut elements.*

*The case test includes/understands two modelings 3D, the loading consists of a load followed by a discharge.*

## 1.2

***Material properties***

***To test the evolution of the mechanical characteristics in an irreversible way with the temperature, one apply a field of temperature decreasing. Certain variables depend on the temperature, others of drying. Lastly, one applies a coefficient of withdrawal of desiccation not no one, equal to thermal dilation coefficient, to test “data-processing” operation. Deformations thermics thus equal and will be opposed to the deformations of withdrawal of desiccation. These dependences intervene only for checks purely data-processing, the characteristics mechanics can be regarded as constants.***

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**The reference solution is calculated in an semi-analytical way, knowing that in traction, only the criterion**

**of traction is activated. It is thus necessary to solve a system of an equation to an unknown factor, which allows**

**to obtain by dichotomy for example, plastic deformation cumulated in traction. This one allows to calculate strains and stresses then. This is possible, knowing displacement, and thus deformation in the two imposed directions. Displacement in the third direction is then an unknown factor of the problem.**

**The reference solution is calculated only in traction. The solution is determined by one program resolution by dichotomy in independent FORTRAN. In compression, discharge, exact solution was not recomputed, and constitutes a solution of nonregression of the code, been dependent on version 5.02.14.**

**For modeling B, the results result by rotation from the tensor from constraint from modeling A, of the intrinsic reference mark of the cube to the reference mark user, the stress field of both configurations being identical in the intrinsic reference mark of the cube.**

## 2.2

### *Calculation of the reference solution of reference*

*For more details on the notations and the setting in equation, one will refer to the document of reference. Only, the principal equations are pointed out here.*

*One notes “has”, imposed displacement following direction  $X$ , and “2.a” following imposed displacement*

*direction  $Z$ . The tensor of deformation is form (has,  $y$ , 2.a, 0. , 0. , 0.) by taking the notations usual of Code\_Aster (three principal components, three components of shearing).*

*The tensor of constraint is form ( $X$ , 0. ,  $Z$ , 0. , 0. , 0.), in modeling A.*

*The criterion of traction is expressed in the form:*

$+ C.$

$2$

$C$

$F$

$Oct.$

$Oct.$

$=$

$- F$

$eq$

$=$

$+ -$

$T (T)$

$F$

$trac$

$H$

$T (T)$

$D$

$D$

$3$

$D$

*The constitutive equations are written by distinguishing the isotropic part of the deviatoric part of tensors of constraints and deformations.*

$1$

## 7

**Summary of the results**

This case test offers satisfactory results compared to the results of reference, lower than 0.06% for the first two cases of loading, more important for the third, which is explained by one relatively low level of constraint (one reaches the end of the curve of work hardening in traction).

The test discharges some (fourth loading) makes it possible to check nonthe regression of the code.

The iteration count is relatively important with the first step of calculation, about 13, then drop to 7, 4 and 1, which is explained by the passage of the plastic threshold to the first step of calculation, for

to reach a quasi linear behavior thereafter (curved post-peak linear).

One obtains also a more significant number of iterations to step 31 (beginning of the fourth case of loading), then an iteration count dropping up to 1, because of the passage in discharge, with one change of behavior, follow-up of a quasi linear behavior thereafter (curved post-peak linear).

## ***Summary of the results***

***The solutions obtained by Code\_Aster are very close to the reference solution of the software The SAMCEF software, with a grid twice less refined. Values of displacement at the end of the beam differ from to the more 2,5% for the first modeling in quadrangle and of to the more 6,7% for the second modeling in triangle.***

***SSNV146 - Analyze regularized limit.  
Spherotoric bottom tank***

***Summary***

***This test makes it possible to qualify the operators used analyzes regularized limit of it. One calculates the load limits by a kinematic approach regularized by the method of Norton-Hoff-Friaâ.***

***One considers an axisymmetric spherotoric bottom tank (modeling A). The constitutive material checks it criterion of von Mises and the structure is subjected to an internal pressure. Calculation makes it possible to obtain the load limit in the direction of the loading.***

***The structure is modelled by incompressible elements and the loading is standardized.***

***The resolution by the regularized method of Norton-Hoff-Friaâ is carried out in the order STAT\_NON\_LINE. A postprocessing in order POST\_ELEM makes it possible to obtain the value of a terminal higher of the limiting load, as well as an estimate of the lower limit.***

***The reference solution results from a European benchmark, carried out within the framework of a project Brite EuRam BE97-4547 "LISA", in 1998, and the results are in perfect agreement with the values of reference. **Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**This test of benchmark is referred: case-test LA6 and was carried out within the framework of a European project**

**Brite EuRam BE97-4547 “LISA”, in 1998, partly financed by the EC. This test was carried out with even grid by the three participating organizations. By considering a pipe of same dimensions, the limiting load is: 4,0005MPa, and for the sphere of same dimensions: 4,04MPa.**

**2.2**

**Results of reference**

**One gives hereafter the results provided by EDF at the time of the benchmark, for three values of the parameter of regularization  $N$ , as those provided by organizations LTAS in Liege (which uses another regularized kinematic method, in the university software dedicated “ELSA”) and ForschungZentrum of Jülich (which use a static method approximate by finite elements in displacements, and one reduced representation of the fields of auto-contraintes, using the Permas code, supplemented of one algorithm of optimization).**

***SSNV148 - Models of Weibull and Rice-Tracey***  
***in 3D and discharge***

***Summary:***

***This test of nonlinear quasi-static mechanics makes it possible to validate the models of Weibull and Rice and Tracey in 3D for nonmonotonous cases of mechanical loadings (cf POST\_ELEM [U4.61.04]).***

***At the temperature of 50°C, a cylindrical test-tube smoothes is first of all deformed up to 10%. After having it slightly discharged, one maintains constant the level of deformation reaches while decreasing way homogeneous the temperature of the test-tube until 150°C. At this new temperature, one applies one additional deformation to reach 15% on the whole. Probability of rupture per cleavage as well as the rate of growth of the cavities of the test-tube are calculated for the whole of the way of loading.***

***The modeling of the test-tube is carried out with elements 3D (HEXA20, PENTA15).***

**Summary of the results**

**The objective of modeling A is to show refermeture of crack in compression after one phase of damaging traction. Modeling B shows the effects of the parameter C**

**threshold**

**(constraint threshold in an unconfined compression test). It should be noted that the constraint threshold**

**does not correspond in calculation exactly to the constraint of initiation of the damage in compression, this is due to the fact that the criterion is evaluated starting from the deformations with the step of time**

**precedent and not with the step of current time. The error observed thus depends on the size of the steps on time.**

of behavior BETON\_DOUBLE\_DP***

***Summary***

***This case of validation is intended to check the model of behavior 3D BETON\_DOUBLE\_DP***

*formulated in*

*tally of thermoplasticity, for the description of the nonlinear behavior of the concrete, in traction, and in*

*compression, with the taking into account of the irreversible variations of the thermal characteristics and*

*mechanics of the concrete, particularly sensitive at high temperature.*

*The description of cracking is treated within the framework of plasticity, using an energy equivalence, by identifying the density of energy of cracking in mode I, with the plastic work of a homogeneous medium*

*equivalent, where the plastic deformation is uniformly distributed, in an “elementary” zone. This approach*

*preserve the continuity of the formulation of the model, on the whole of its behavior, and contributes to avoid*

*possible numerical difficulties during the change of state of material.*

*Pathological sensitivity of the numerical solution to the space discretization (grid), generated by the introduction of a softening behavior of the concrete in traction and compression, is partially solved*

*by introducing an energy of cracking or rupture, dependent a characteristic length  $l_c$ , related to cut elements.*

*The resolution of the equations constitutive of the model is carried out by an implicit scheme.*

*It is about a cube with 8 nodes subjected to a triaxial traction, in imposed displacement. This led loading*

*with the particular case of a hydrostatic state of stress, solved by projection at the top of the cone of traction,*

*when one places oneself in a hydrostatic diagram forced equivalent/forced. It is about a case test with analytical solution.*

## ***Reference solution***

***2.1***

### ***Method of calculation used for the reference solution***

*The reference solution is calculated in an analytical way, knowing that in traction, only the criterion of traction is activated, and that in the case of a hydrostatic loading, one is projected at the top of cone of traction. It is thus necessary to solve a linear system of an equation to an unknown factor, which allows*

*to obtain the plastic deformation cumulated in traction. This one makes it possible to calculate then strains and stresses.*

***2.2***

### ***Calculation of the reference solution of reference***

*For more detail on the notations and the setting in equation, one will refer to the reference document [R7.01.03]. Only, the principal equations are pointed out here.*

*One notes “has”, imposed displacement following directions X, y and Z. The tensor of deformation is form (has, has, has, 0. , 0. , 0.) by taking the usual notations of Code\_Aster (three components principal, three components of shearing).*

*The tensor of constraint is form (, 0. , 0. , 0.), in modeling A.*

### ***General equations of the model:***

*The equations constitutive of the model are written by distinguishing the isotropic part of the part deviatoric of the tensors of constraints and deformations.*

***1***

***1***

$$\begin{aligned}
 &I \\

### **Summary of the results**

*This case test offers very satisfactory results compared to the analytical solution, lower than 7.10- 5% with a low iteration count (1 or 2 iterations). The solution is obtained from one linear equation in the case of a linear curve of work hardening in traction, but the resolution uses an algorithm of Newton within a framework plus general.*

*One can note the work hardening of the criterion of traction which takes place during the loading, involving one*

*reduction in the constraint (component *xx*, *yy* and *zz*) in addition equalizes with the hydrostatic constraint.*

***SSNV151 - Traction/Compression with the law of  
behavior BETON\_DOUBLE\_DP***

***Summary***

***This case of validation is intended to check the model of behavior 3D BETON\_DOUBLE\_DP  
formulated in***

***tally of thermoplasticity, for the description of the nonlinear behavior of the concrete in traction and  
in***

***compression, with the taking into account of the irreversible variations of the thermal characteristics  
and***

***mechanics of the concrete, particularly sensitive at high temperature.***

***The description of cracking is treated within the framework of plasticity, using an energy equivalence,  
by identifying the density of energy of cracking in mode I, with the plastic work of a homogeneous  
medium***

***equivalent, where the plastic deformation is uniformly distributed in an “elementary” zone. This  
approach***

***preserve the continuity of the formulation of the model, on the whole of its behavior, and contributes***

*to avoid possible numerical difficulties during the change of state of material.*  
*Pathological sensitivity of the numerical solution to the space discretization (grid), generated by the introduction of a softening behavior of the concrete in traction and compression, is partially solved by introducing an energy of cracking or rupture, dependent a characteristic length  $l_c$ , related to cut elements.*  
*The resolution of the equations constitutive of the model is carried out by an implicit scheme.*  
*It is about a cube with 8 nodes subjected to a uniaxial pressing, in imposed displacement to which is added a biaxial traction when one reached an important work hardening in traction. This loading led to the case private individual of a hydrostatic state of stress, solved by projection at the top of the cone of traction, when one places oneself in a hydrostatic diagram forced equivalent/forced. It is about a case test of not regression.*

## 1.2

### **Material properties**

*To test the establishment of thermal dilation and the withdrawal of desiccation, a field is forced of temperature and a field of drying variables so that deformations generated by the two phenomena are compensated, while considering that the dilation coefficients thermal and of withdrawal of desiccation are equal. The values related to drying do not have any physical direction, it test is from this point of view, purely data-processing.*

### **For the usual linear mechanical characteristics:**

*Young modulus:*

$$E = 32.000 \text{ MPa}$$

*Poisson's ratio:*

$$= 0.18$$

*Thermal dilation coefficient:*

$$= 105/^{\circ}\text{C}$$

*Coefficient of withdrawal of desiccation:*

$$= 10^{-5}$$

*Temperature of reference*

$$T_{\text{ref}} = 0 \text{ }^{\circ}\text{C}$$

*Drying of reference*

$$C_{\text{ref}} = 20$$

**Results of modeling A****3.1 Values****tested**

Were tested components  $xx$  and  $yy$  of the stress field *SIEF\_ELNO\_ELGA*, the deformation figure cumulated in compression, plastic deformation cumulated in traction (first and second internal variable, second component of field *VARI\_ELNO\_ELGA*) and the plastic state (fourth variable of field *VARI\_ELNO\_ELGA*). The plastic state is worth 1 in compression, 11 afterwards projection at the top of the cone of compression, 2 in traction, 22 after projection at the top of the criterion of traction, 3 in compression and traction together, and 33 after projection out of the two tops of two cones. Displacement being imposed, field *EPSI\_ELNO\_DEPL* is not tested. The values given here correspond to version 7.2.25.

***Summary:***

***This problem corresponds to a quasi-static analysis of a problem of mechanics with contact without friction. It is about a cord posed on a pulley, whose interior surface is embedded, and drawn from two sides with an imposed vertical displacement.***

***This test, treated in 2D with elements QUAD4 is implemented to validate the smoothing of the normal of surfaces of contact.***

***This test is based on results 2D suggested by Papadopolous [bib1].***

### **Summary of the results**

*In this case test, two surfaces of contact are not plane. The normal thus changes one net with another. This discontinuity generates problems of pairing which have large influence on calculation. Among these problems, one finds the problem of dissymetrisation, i.e to find results which do not respect the symmetry of the problem. For this case test, the problem is perfectly symmetrical (geometries, boundary conditions and loading) according to axis Y. Without regularization of the normal a dissymmetry appears on axis X. Indeed, displacements horizontal of the points A, B and C which are on the axis have there then nonnull values which do not respect the total symmetry of the problem.*

*With the regularization of the normal, the solution obtained by using the method continues, respects perfectly symmetry. It should however be noted that the maillor gibi, used in this case test, does not give*

*not a perfectly symmetrical grid and that problems of round-offs deteriorate very slightly the quality of the solution.*

*This problem is dealt with with the method CONTINUES, of the key word CONTACT. Integration is made with level of the nodes of the grid. A detailed attention on the choice of the potential zones of contact is to be taken into account in these problems of nonplane surfaces.*

**SSNV154 - Triaxial compression test drained with model CJS**

**(level 3)**

## **Summary**

***This test makes it possible to validate level 3 of model CJS. It is about a triaxial compression test in drained condition.***

***calculations are carried out only on the solid part of the ground without hydraulic coupling. The level of containment is 400 KPa.***

***By reason of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test. Two***

***modelings are presented. Modeling A is axisymmetric. In modeling B, 3D, the sample tested is turned of an angle of  $-\pi/6$  compared to axis X. Consequently, directions X, y, Z are not any more principal directions. That makes it possible to validate the operations of numerical integration of the model which act on***

***nondiagonal terms of the tensors of the strains and the stresses.***

***It is about a test of nonregression. Nevertheless, results obtained with Code\_Aster for model CJS3 are compared with those obtained with a private version of software FLAC 2D.***

**SSNV155 - Triaxial compression test drained on a sample  
turned of an angle of  $\pi/6$  compared to axis X with  
model CJS (level 2)**

**Summary**

**This test makes it possible to supplement the validation of level 2 of model CJS already approached in the case test SSNV136.**

**It corresponds to the digital simulation of the same test (drained triaxial compression test) on same material but with**

**a different geometry. The sample tested is thus turned of an angle of  $\pi/6$  compared to axis X. By consequent, directions X, y, Z are not any more principal directions. That makes it possible to validate the operations**

**of numerical integration of the model which acts on the nondiagonal terms of the tensors of the deformations and constraints.**

**As for the case test SSNV136, calculations are carried out only on the solid part of the ground, without**

*hydro-mechanical coupling. By reason of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test. The level of containment is of 400 kPa It is about a test of nonregression. The results obtained are compared with those provided by an Aster calculation with a grid whose axes of symmetry are the axes of co-ordinates. They correspond to them exactly with the rotation of angle  $\pi/6$  near.*

***SSNV156 - Column under voluminal loading.***  
***Elastoplastic law has gradient***

***Summary:***

***In addition to the elastoplastic law with gradient which it tests only in its version with linear work hardening, this test has especially for object to validate the algorithm of integration of the laws of behavior to gradient of internal variables. In effect, the problem suggested, the setting in traction of a column under voluminal forces, led to a solution nonhomogeneous which activates the various components of algorithm (Newton, linear research, BFGS) and for which one can obtain an analytical expression. The results obtained are in agreement with this one, and it with a high degree of accuracy.***

## ***Problem of reference***

### ***1.1 Geometry***

***The structure is a cylinder, with the direction more general, height  $L = 2$  mm and of which the form of section does not influence the solution. So one will adopt a square section for modelings in plane deformations and 3D (side has = mm***

***1***

,

***0***

***) as well as a circular section for axisymmetric modeling (ray  $R =$  mm***

***1***

,

***0***

***).***

### ***1.2***

#### ***Properties of material***

***The material follows an elastoplastic law of behavior to gradient whose work hardening is isotropic and linear. Characteristics of material, respectively the Young modulus  $E$ , the coefficient of  $NAKED$  Poisson, elastic limit  $SY$ , the slope of work hardening  $D\_SIGM\_EPSI$  and the length characteristic  $LONG\_CARA$ , are equal to:***

**$E = 100$   
MPa**

**000**

**= ,  
0 3**

**y =  
MPa**

**100**

**$T$   
 $E = 10$   
MPa**

**000**

**$L$**

**$B =$   
,  
0 982707 mm**

### **1.3 Boundary conditions and loading**

**Vertical displacements are blocked on its higher face, horizontal displacements are blocked on the side faces and the lower face is free of any kinematic condition. By elsewhere, the structure is subjected to a voluminal force vertical and directed to the bottom of intensity**

**increasing  $F T$**

**$() = F T$  where**

**3**

**$F =$   
1 N/mm and  $T$  is a parameter of loading (without unit).**

**0**

**0**

**Handbook of Validation

**14/10/02**

**Author (S):**

**E. Key LORENTZ**

:

**V6.04.156-A Page:**

**3/8**

**2**

**Reference solution**

**2.1**

**Method of calculation of the reference solution**

***This problem admits an analytical solution. Sought sizes, namely the constraints, deformations, plastic deformations  $p$***

***and cumulated plastic deformation  $p$ ,***

***depend that level on loading  $T$  and dimension  $Z$  of the section considered, where  $Z = 0$***

***indicate the lower face (free) cylinder and  $Z = L$  its face higher (blocked).***

***Because of the blocking of the side faces, the sections do not become deformed horizontally, so that the fields of displacements and deformations are written:***

**$U(Z, T) = U(Z, T) E$**

**$(Z, T)$**

**$Z$**

**$= (Z, T) e_z E$**

**with**

**$U(L, T)$**

**$Z$**

**$= 0$  éq 2.1-1**

***As for the tensor of constraints, it is diagonal. Its vertical component is fixed by the equation of balance while its horizontal components, identical in the two directions, depend law of behavior (effect of fastening):***

$$\begin{aligned} (Z, T) &= S (Z, T) (e_x e_x + e_y e_y) + (Z, T) e_z E \\ \text{with} \\ Z \\ (Z, T) &= Z F (T) \text{ \textit{\'eq}} \\ 2.1-2 \end{aligned}$$

*One can notice that the evolution of the diverter of the constraints is radial:*

$$\begin{aligned} D \\ 1 \\ 2 \\ &= e_q - (e_x e_x + e_y e_y) + e_z E \\ \text{and} \\ Z \\ &= - S \\ e_q \\ \text{ \textit{\'eq}} 2.1-3 \\ 3 \\ 3 \end{aligned}$$

*Having proposed a field of displacements kinematically acceptable and a stress field statically acceptable, it any more but does not remain to show than they are bound by the law of behavior. Well that it is about a nonlocal model, the law of flow preserves its usual form:*

$$\begin{aligned} D \\ p \\ 3 \\ p \\ 1 \\ \& = p\& \\ &= p - (E \\ E \\ E \\ E \\ E \\ E \text{ \textit{\'eq}} \\ 2.1-4 \\ X \\ X + \end{aligned}$$

y  
y)

+ Z Z  
2 eq  
2

*The same applies to the relation stress-strain, where and  $\mu$  is the coefficients of Lamé which result from the Young modulus and the Poisson's ratio:*

= (tr) Id +  $\mu$   
2 (  
p  
-)  
2.1-5

*While deferring [éq 2.1-1], [éq 2.1-2] and [éq 2.1-4] in [éq 2.1-5], one deduces the expression from it from constraints and of the deformations according to the only cumulated plastic deformation:*

1 E  
2 2 Z F

S =  
p + Z F  
= 1-  
+ 1-  
p

éq 2.1-6  
1 - 2  
1 - E

1-

**Handbook of Validation****V6.04 booklet: Nonlinear statics of the voluminal structures****HT-66/02/001/A****Code\_Aster ®****Version****6.0****Titrate:****SSNV156 - Column under voluminal loading****Date****:****14/10/02****Author (S):****E. Key LORENTZ****:****V6.04.156-A Page:****4/8**

***The condition of coherence then makes it possible to determine  $p$ . Insofar as the evolution of the diverter***

***constraints is radial and monotonous, one can directly determine the current state without having with***

***to integrate the rate of plastic deformation. Indeed, one can distinguish two zones in the structure: one,  $0 \leq B$ , in which the plastic deformation is null and where the threshold of plasticity is not reached, and the other,  $B \leq L$ , where the plastic deformation is nonnull and the threshold reached. The border  $B$***

***between these two zones is a new unknown factor of the problem. As follows:***

$$0 \leq B \leq p = 0$$

**éq****2.1-7**

$$B \leq L \quad F = 0$$

***According to [bib1], the threshold of plasticity has as an expression:***

 **$T$**  **$2$**  **$($**  **$E E$**  **$H L$**

$$F p) \\ y \\ 4 \\ , \\ B \\ = e q - H p - + C p$$

where

$$H =$$

and

$$C =$$

$$\acute{e}q$$

$$2.1-8$$

$$T$$

$$E - E$$

$$13$$

Moreover, always according to [bib1], the field of cumulated plastic deformation  $p$  is 1  
 $C$  and of derivative  
 null at the edge of the structure. That implies in particular:

$$p(b) = 0$$

$$p(b) = 0$$

$$p(L) = 0$$

$$\acute{e}q$$

$$2.1-9$$

Taking into account [éq 2.1-7] and [éq 2.1-8],  $p$  checks a linear differential equation of the second order on the field  $B \ Z \ L$ :

$$E$$

$$1- 2$$

$$y$$

$$C p (Z) +$$

$$+$$

$$()$$

$$\acute{e}q$$

$$2.1-10$$

$$2 (1 -) H p Z$$

$$=$$

$$Z F -$$

$$1-$$

*The data of the 3 boundary conditions [éq 2.1-9] then makes it possible to determine  $p$  completely like the position  $B$  of the free border.*

*To reduce the expressions, the following notations are introduced:*

$E$

$C$

$4 H$

$1-2$

$H = ($

$H$

$L$

$L$

$F$

$2 1- ) +$

$C =$

$= B$

$=$

$H$

$13 H$

$H (1 -)$

*éq 2.1-11*

$y$

$Z - L$

$Z - L$

$(Z) = Z -$

$C (Z) = \cosh$

$S (Z) =$

$\sinh$

$H$

$L$

$L$

$C$

$C$

*Then, after some calculations, one obtains the following expression for  $p$ :*

*L*  
*S (b)*  
*B*  
*( )*  
*C*  
*-*  
*With =*  
*p (Z) = (Z) + AC (Z) + BS (Z)*  
*where*  
*C (b)*

*éq 2.1-12*

*B = - Lc*  
*As for the free border, it is given according to the level of loading by the equation following (or conversely, the level of loading corresponding to a certain position of free border):*

*y*  
*S (b)*  
*=*  
*éq*  
*2.1-13*  
*H bS (b) + L*  
*-*

## 9 **Summary of the results**

*Because of the positive character of work hardening, the problem exhibe not of instabilities, which confirms good convergence of calculations. The validation relates thus to the law of behavior itself and on the algorithm of integration of the nonlocal laws, from which the various components are activated (primal and dual iterations observed). The remarkable agreement enters the values of reference and those calculated shows the capacities of the algorithm when a fine precision is necessary (criteria of convergence severe) while the size of the dealt with problems, particularly in 3D, seems to prove its robustness.*

***SSNV158 - Triaxial compression test drained with the model of  
Laigle***

***Summary***

*This test makes it possible to validate the model of Laigle in rock mechanics (formalism CIH). It is about a test triaxial in drained condition. Calculations are carried out only on the solid part of the ground without coupling hydromechanics. Four levels of containment are applied (8 MPa 4 MPa 2 MPa 1 MPa). By reason of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test. Modeling is axisymmetric.*

*It is about a test of nonregression. Nevertheless, the results obtained with Code\_Aster were post-treaties with Excel and compared with those obtained with a private version of software FLAC-2D. Handbook of Validation V6.04 booklet: Nonlinear statics of the voluminal structures HT-66/04/005/A*

***SSNV160 - Hydrostatic test with the law  
CAM\_CLAY***

***Summary:***

*This test makes it possible to validate the mechanical law elastoplastic Cam\_Clay specific to the*

grounds normally

consolidated the elastic part is non-linear and the plastic part is hardening or lenitive. It test is a hydrostatic test of compression. These results are compared with an analytical solution for two modelings 3D and axisymmetric. Modelings has and B which called upon linear research are reabsorbed, this is why only modelings C and D are written.

$E = 4.2E7 Pa$

$= 0.285$

= .

0

*Parameters specific to CAM\_CLAY:*

*PORO = 0.14, = 0.25, = 0.05, M = 0.9, CLOSE \_ CRIT = .  
3 E5 Pa, Pa = 1.E5 Pa*

### **1.3**

#### ***Boundary conditions and loadings***

*The hydrostatic test is carried out with a state of homogeneous stresses:*

*= = = P. One*

*xx*

*yy*

*zz*

*fact a first elastic design to  $P = P_a$ . One increases then  $P$  to  $P$  while carrying out  
sup*

*a loading with Cam\_Clay followed by a discharge to  $P_a$ .*

### **1.4 Conditions**

#### ***initial***

*In CAM\_CLAY, the elastic law requires a hydrostatic constraint in an initial state (the deformation  
being  
null).*

*To initialize this constraint, one chose to carry out at the beginning a purely elastic calculation in  
making evolve/move pressure of 0. with 1.E5 Pa. One extracts from this calculation only the field of  
constraints at the points of gauss. This stress field resulting from the elastic design is considered  
like the initial state of the hydrostatic constraint necessary to the law Cam\_Clay of following  
calculation.*

## **Reference solution**

2.1

### **Method of calculation**

*tr* ( )

*In a hydrostatic test:*

*= = and the hydrostatic constraint is  $P = -$*

*xx*

*yy*

*zz*

3

*(convention of the soil mechanics).*

*For the calculation of the total voluminal deformation, one distinguishes the two cases:*

***1st case:*** *Case of non-linear elasticity, the hydrostatic pressure is lower than the pressure of consolidation:*

$$P < P < 2P$$

$$0 = P$$

*atm*

*Cr*

*ion*

*consolidat*

*l*

*P*

$$P = P \exp ($$

*E*

*K) or E*

*=*

*Ln*

*atm*

*0 v*

*v*

$K$   
 $P$   
 $0$   
 $atm$

*in this case the total deflection is equal to the elastic strain:*

$E$   
 $=$   
 $v$   
 $v$

**2nd case:** *Case of plasticity, the hydrostatic pressure exceeded the pressure of consolidation, there is thus hardening:*

$P > 2P = P$   
 $, P = 2P$  *after plasticization.*  
 $Cr$   
*ion*  
*consolidat*  
 $Cr$

*and the critical pressure evolves/moves as follows*

$P = P \exp (p$   
 $K)$   
 $Cr$   
 $cr0$   
 $v$   
 $P$   
 $p$   
 $1$   
 $1$   
 $P$

*and voluminal deformation:*

$Cr$   
 $= Ln$   
 $= Ln$

$v$   
 $K$   
 $P$   
 $K$   
 $2P$   
 $cr0$

*cr0*

*In this case, it is necessary to take into account the plastic deformation in the calculation of the total deflection*

*E*

*P*

*l*

*P*

*l*

*P*

*: = + =*

*Ln*

*+ Ln*

*v*

*v*

*v*

*K*

*P*

*K*

*2P*

*0*

*atm*

*cr0*

**2.2**

***Sizes and results of reference***

*The test is homogeneous. One tests the voluminal deformation in an unspecified node where components are equal: =*

*=*

*xx*

*yy*

*zz*

**2.3**

***Uncertainties on the solution***

*None. Exact analytical result.*

***SSNV162 - Calculation of creep of dessication  
intrinsic with the model of Bazant***

***Summary:***

***This test makes it possible to validate the model of intrinsic creep of dessication of Bazant. This type of creep start under the effect of the drying accompanied by a mechanical loading. The results of this test are compared with the analytical solution for two plane forced modelings and 3D.***

part

viatoric

spherical

*By operating a spherical/deviatoric decomposition identical to that of the constraints, axial deformation is written in the form:*

$= f_s$

$z_z$

(

$f_d$

0

)  $3 + (20) 3$

$\epsilon_q$

**2.1-3**

*It is thus necessary successively to solve the response to a level of spherical constraint and one level of deviatoric constraints.*

## 2.2

***Resolution of the equations constitutive of spherical creep [bib2]***

*The process of deformation spherical of creep is controlled by the system of coupled equations according to (equations [  q 2.2-1] and [  q 2.2-2], cf [R7.01.06]):*

$$\begin{aligned} & f_s \\ & \& = 1 H - K - \\ & \textbf{  q} \\ & \textbf{2.2-1} \end{aligned}$$

$$\begin{aligned} & S [ \\ & S \\ & S \\ & f_s \\ & R \\ & R] \\ & f_s \\ & I \\ & \& \\ & R \end{aligned}$$

*where S  
Kr indicates rigidity connect associated with the skeleton formed by blocks with hydrates on the scale mesoscopic;  
and S  
R viscosity connect associated with the mechanism with diffusion within capillary porosity.*

$$\begin{aligned} & f_s \\ & I \\ & I \\ & \& = \\ & K \\ & K \\ & K \end{aligned}$$

$$\begin{aligned} & H \\ & K \end{aligned}$$

$$\begin{aligned} & \textbf{  q} \\ & \textbf{2.2-1} \\ & S [Sr \\ & f_s - (Sr + if) f_{si}] - [S - S f_s \\ & R \\ & R] + \end{aligned}$$

$$I$$

where  
 $S$   
 $k_i$  indicates rigidity connect intrinsically associated with the hydrates on the scale  
microscopic;  
and  $S$   
 $I$  viscosity connects associated with the interfoliaceous mechanism of diffusion.

+

+

1

In [eq 2.2-2], hooks  
appoint the operator of Mac Cauley:  $X$   
 $= (X + X)$

2

The resolution of the preceding system of coupled equations requires to distinguish two cases according to  
sign quantity ranging between the hooks of Mac Cauley. In the continuation, one presents  
analytical resolution of the response to a level of constraint  
 $S$   
. The relative humidity is supposed  
invariant; the medium is saturated with water.

### 2.2.1 Case of short-term creep

At the initial moment,  $T = 0$ , one applies a spherical constraint  $S$   
positive. Deformations of creep

*reversible and irreversible are equal to zero (initial conditions). The equation of the system [éq 2.2-2] is thus written:*

*f<sub>s</sub>*  
*&*

*I (*  
*+*  
*+*  
*T =)*  
*1*  
*0 =*  
*K*  
*K*

***éq***  
***2.2.1-1***  
*S [2 Sr 0 - S*  
*I -*  
*S]*  
*1*  
*0*  
*=*  
*[- S*  
*S*  
*] = 0*  
*I*  
*I*

*The speed of irreversible deformation of creep is thus equal to zero. One deduces from it that irreversible deformation of creep is also equal to zero. The speed of deformation unrecoverable remains equalize to zero until the moment  $T = t_0$ , defined by the relation [éq 2.2.1-2]:*

*S*  
*S*  
*f<sub>s</sub>*  
  
*2 Kr R (t<sub>0</sub>)*  
*S*  
*f<sub>s</sub>*  
*- = 0 R (t<sub>0</sub>) =*

***éq***  
***2.2.1-2***  
*S*

2 Kr

Until the moment  $T = t_0$ , the reversible deformation of creep is defined by the following relation:

S

S

l

T

&r =

K

T

l exp

éq

2.2.1-3

S [S - Sr Sr]

Sr () =

-

-

S

K

S

R

R

R

S

S

R

R =

is the characteristic time associated the reversible deformation of creep. The moment T is

S

0

Kr

thus defined by the relation [éq 2.2.1-4]:

$$\begin{aligned}
 & f_s \\
 & T \\
 & 0 \\
 & R(t_0) \\
 & S \\
 & S \\
 & = \\
 & = \\
 & 1 - \exp - \\
 & t_0 = \ln(2) S \\
 & S \\
 & R_{0.69} R \text{ éq} \\
 & \mathbf{2.2.1-4} \\
 & S \\
 & S \\
 & S \\
 & 2 K \\
 & R \\
 & Kr \\
 & R
 \end{aligned}$$

The reversible and irreversible deformations of creep are thus determined by:

$$\begin{aligned}
 & S \\
 & f_s ( \\
 & T) \\
 & T \\
 & =
 \end{aligned}$$

$$\begin{aligned} &R \\ &S \\ &1 - exp - S \end{aligned}$$

$\exp (2 T)$

2

*One can then return to initial space, by the means of the matrix of passage; deformations of creep reversible and irreversible are linear combinations of \**

*1 and \**

*2. Eigenvalues*

*matrix A, 1*

*and 2 are obtained while solving:*

$\det (A - I)$

$1 = 0$

$- u_{rr} - 4 u_{ri} -$

2

I

U

*éq 2.2.2-8*

$$\begin{aligned}
 &II \\
 &= 0 \\
 &2 \\
 &I + (urr + 4uri + uii) I + urr uii = 0 \\
 &2 uri \\
 &- uii - I
 \end{aligned}$$

By noticing that  $urr$ ,  $uri$  and  $uii$  are strictly positive, the discriminant is thus always strictly positive. The eigenvalues are thus real and distinct, matrix  $A$  is thus diagonalisable. In addition, none of the two eigenvalues is equal to zero

$$\begin{aligned}
 &(= urr uii \neq 0 \\
 &1 \\
 &2 \\
 &). \text{ The two eigenvalues are defined by:}
 \end{aligned}$$

$$\begin{aligned}
 &- (urr + 4uri + uii) - \\
 &1 \\
 &=
 \end{aligned}$$

 &2 \\
 &\text{éq} \\
 &\mathbf{2.2.2-9}
 \end{aligned}$$

$$\begin{aligned}
 &- (urr + 4uri + uii) + \\
 &2 = \\
 &2
 \end{aligned}$$

One can show that the two eigenvalues are indeed negative. Let us show that second eigenvalue is negative. The spherical deformation of creep is thus asymptotic, assumption put forth in the model of clean creep spherical [bib1]. Let us determine one now base clean vectors  $(X_1, X_2)$  associated the eigenvalues 1 and 2. It is determined in solving equation  $(A - I) X = 0$ . A particular base of clean vectors is written:

$$\begin{aligned}
 &x_1 \\
 &1 \\
 &1 \\
 &+ uii
 \end{aligned}$$

2 uri  
X 1 =  
and X

2 =  
with X

1 =  
and x2 =

where

$D$

*I indicates the viscosity of interstitial water. The system of equations [éq 2.3-2] and [éq 2.3-3] is more simple to solve than that governing the spherical behavior owing to the fact that it is uncoupled. One always suppose that moisture remains equal to 1 during all the loading. The equation [éq 2.3-2] corresponds to the viscoelastic model of Kelvin whose response to a level of constraint is of exponential type. As for the equation [éq 2.3-3], the response in deformation is linear with time. The total deformation of creep is thus written as the sum of the contribution of a chain of Kelvin and of the contribution of a shock absorber and series:*

***SSNV164 - Setting in tension of cables of  
prestressed in a beam 3D***

## **Summary**

*One considers a concrete beam reinforced with section square, composed of two sections of 10 meters length, having respectively one and four square meters of section. The beam is vertical, weakest section in bottom. It is embedded at its base, and contains 5 rectilinear cables of prestressing. One tests here the phasage setting in prestressing, i.e. the setting in successive tension of different cables.*

*The functionalities particular to test are as follows:*

- *operator DEFI\_CABLE\_BP: determination of the relations kinematics between the DDL of the nodes of a cable and DDL of the nodes “close” to a concrete structure modelled by elements 3D and calculation of the tensions in a cable under the friction effect and of the retreat of anchoring,*
- *operator AFFE\_CHAR\_MECA associated with key word RELA\_CINE\_BP,*
- *operator CALC\_PRECONT: setting in tension of the cables of prestressing.*

*The results obtained are validated by comparison with the computer code CASTEM 2000.*

*Handbook of Validation*

*V6.04 booklet: Nonlinear statics of the voluminal structures*

*5  
1m*

*2  
4  
0.225m*

*The five cables which cross all the length of the beam are located as on plan Ci below:*

*Appear 1.1-a: Positioning of the cables in the beam*

*The section of each cable is 25 cm<sup>2</sup>.*

## *1.2 Properties of materials*

*Material concrete constituting the beam:*

*• modulus Young:*

*$E_b = 4.105 \text{ MPa}$*

*• Poisson's ratio:*

*$= 0,2$*

*• density:*

*$= 2500 \text{ kg/m}^3$*

*Material steel constituting the cable:*

*• modulus Young:*

*$E_b = 1,93 \text{ } 10^5 \text{ MPa}$*

*• Poisson's ratio:*

*$= 0,3$*

*• density:*

*$= 7850 \text{ kg/m}^3$*

*Characteristic concerning the setting in tension of the cables:*

*• retreat of anchoring = 1 mm*

*• linear coefficient of friction: 0,0015 M-1*

*• force of tension at the end of a cable: 3,75 10<sup>6</sup> NR*

*• age of dismantling 150 days*

· *age of setting in tension of the first cables 300 days*

***Boundary conditions and loadings***

***The base of the beam is blocked in direction Z. the two translatory movements per report/ratio with OX and OY are blocked as well as the rotational movement around OZ.***

***The sequence of loading is as follows:***

- ***at 300 days, put in tension of 2 cables (1 and 2) by their lower end,***
- ***at 450 days, put in tension of 2 additional cables (3 and 4) always by their end lower,***
- ***at 600 days, put in tension of the last cable (5) by its two ends.***

***The beam is obviously subjected to gravity.***

***2***

***Reference solution***

***The reference solution was obtained by the ECA with CASTEM 2000, with a grid containing 2080 cubic elements with 20 nodes and 100 elements of cable.***

### **3 Modeling**

**With**

#### **3.1**

##### ***Characteristics of modeling***

***The concrete beam is represented by 2080 elements MECA\_HEXA8, supported per as many meshes hexahedrons with 8 nodes. The 5 cables are represented using 20 elements MECA\_BARRE each one supported per as many segments with 2 nodes. The figure below shows the grid of the beam.***

##### ***Appear 3.1-a: Description of the grid***

***The material concrete is defined by behaviors ELAS and BPEL\_BETON: parameters characteristics of this relation are fixed at 0 but one does not wish to include the losses of tension had with the shrinking and the creep of the concrete.***

***The material steel for the cables is defined by behaviors ELAS and BPEL\_ACIER. nonnull values for BPEL\_ACIER relate to friction (FROT\_LINE=1,5 10<sup>-3</sup> M<sup>-1</sup>) and the limit of elasticity since a zero value is illicit (SY = 1,94 10<sup>11</sup> Pa). The ray of the cables is 2,8209 10<sup>-2</sup> Mr.***

***The blocked DDL are as follows:***

***DZ for the lower face***

***DX and DY for the points located on the axis of symmetry of the beam***

***DX for the point (0.5 0. 0.) and DY for the point (0.5 0. 0.)***

*The F0 tension = 3,75 106 NR is applied to the lower nodes of cables 1, 2, 3 and 4 and to both ends for cable 5.*

*:*

*V6.04.164-A Page:*

*5/8*

*The loading is carried out in 4 steps of time:*

- T = 150 S, taken into account of gravity: STAT\_NON\_LINE with the boundary conditions, gravity and the relations kinematics for all the cables. Cables not contributing with the rigidity of the model, one affects a law of behavior to them “WITHOUT” (null constraint),*
- T = 300 S, put in tension of cables 1 and 2: CALC\_PRECONT with the boundary conditions, cables 1 and 2 being cables to be put in tension, cables 3, 4 and 5 being inactive,*
- T = 450 S, put in tension of cables 3 and 4: CALC\_PRECONT with the boundary conditions, the relations kinematics for cables 1 and 2, cables 3 and 4 being cables to be put in tension, cable 5 being inactive,*
- T = 600 S, put in tension of cable 5: CALC\_PRECONT with the boundary conditions, them relations kinematics for cables 1, 2, 3 and 4, cable 5 being the cable to be put in tension.*

*3.2*

*Stages of calculation and functionalities tested*

*The principal stages of calculation correspond to the functionalities which one wishes to validate:*

- operator DEFI\_MATERIAU: definition of the relations of behavior BPEL\_BETON with default values and BPEL\_ACIER, in the case of loss by linear friction,*
- operator DEFI\_CABLE\_BP: determination of a profile of tension along the cable of prestressed, by taking of account losses by linear friction and losses by retreat*

*of anchoring; calculation of the coefficients of the relations kinematics between the DDL of the nodes of cable and the DDL of the nodes “close” to the beam out of concrete, in the case of a beam modelled by elements 3D,*

*· operator*

**AFFE\_CHAR\_MECA**

*: definition of a loading of the type*

**RELA\_CINE\_BP** (**RELA\_CINE** = ' OUI'),

*· operator STAT\_NON\_LINE, option COMP\_INCR: calculation of the state of balance by holding account*

*loading of the type RELA\_CINE\_BP, in the case of a beam modelled by elements 3D,*

*· law of behavior WITHOUT,*

*· macro-order CALC\_PRECONT with a nonvirgin initial state, that there is or not inactive cables, that there are one or more cables to put in tension.*

### *Summary of the results*

*It is noted that the macro-order makes it possible to obtain the tension given by the BPEL (guaranteed by procedure implemented by CASTEM) with a very good precision since the variation is lower than 0.1%. In addition, the effect of the setting in tension of the cables on the remainder of the structure and in particular on the already tended cables, is completely satisfactory since the variation enters the reference solution and it aster calculation is lower than 1%, whereas the grid of reference was quadratic and calculation carried out here used linear meshes.*

*SSNV165 - Triaxial compression test not drained with the law  
CAM\_CLAY*

*Summary:*

*This test makes it possible to validate the mechanical law elastoplastic Cam\_Clay specific to the grounds normally consolidated. This law integrates an elastoplastic hydrostatic mechanism (of which the elastic part is non-linear and the threshold of flow corresponds to the pressure of consolidation) coupled to a deviatoric elastoplastic the elastic part is linear. The behavior is hardening or softening according to the combination of the two mechanisms. This test carried out in hydro-mechanical coupling includes/understands two ways of loading: 1) a hydrostatic way of compression in condition drained until the pressure of consolidation, 2) a way not-drained by maintaining the pressures lateral confining on the sample and by imposing one*

*vertical displacement of compression which induces a triaxial state of stresses.*

*Modeling is carried out in 3D.*

3 E5 Pa, Pa = 1.E5 Pa*

### *1.3*

#### *Boundary conditions and loadings*

*The first way of loading is carried out with a state of hydrostatic stresses:  
= = = P. One makes a first elastic design to P = Pa (to establish an initial state).*

*xx*

*yy*

*zz*

*One increases then P to P*

*= P*

*= .*

*6 E5Pa = 2P by using Cam\_Clay,*

*sup*

*ion*

*consolidat*

*Cr*

*pressure of water is null*

*l*

*PRE = 0 (drained condition). For the second way, one maintains  
pressure P on the side faces and one imposes then a vertical displacement imposed in  
compression to model a triaxial compression test, calculation is now not drained, which corresponds  
to  
a hydrostatic flow no one on all the faces.*

### *1.4 Conditions*

#### *initial*

*In CAM\_CLAY, the elastic law requires a hydrostatic constraint strictly higher than zero with  
the initial state (deformation being null).*

*To initialize this constraint, one chose to carry out at the beginning a purely elastic calculation in  
making evolve/move pressure of 0. with 1.E5 Pa. One extracts from this calculation only the field of  
constraints at the points of gauss. This stress field resulting from the elastic design is considered  
like the initial state of the hydrostatic constraint necessary to the law Cam\_Clay of following  
calculation.*

## *Summary of the results*

*tr* ()

*By interpreting the diagram,  $(P, Q)$ ,  $P = -$   
and  $Q = - (-)$  in the case of this case test, one*

3

3

1

*note well that the loading remains hydrostatic up to a value of 6.E5Pa. Once it  
vertical displacement is imposed and varies with time, the pressures on the side faces being  
maintained constant, a diverter of constraints is induced and increases with time with one  
positive work hardening. When one approaches the point  $Q = MP$ , one tends towards perfect plasticity  
with  
plastic flow without work hardening and variation of constraints (see [§6] Doc.  
[R7.01.14]).*

***V6.04 booklet: Nonlinear statics of the voluminal structures***  
***Document: V6.04.166***

***SSNV166 Rolls fissured under loadings multiples***

***Summary***

***The purpose of this test is calculation of the stress intensity factors along the bottom of crack for a cylinder comprising an axisymmetric crack.***

***The influence of the degree of the elements and the type of the method is studied through various modelings.***

- Modeling A tests K1 and K3 with a linear grid 3D and a method with the finite elements traditional (FEM).***
- Modeling B tests K1 and K3 with a quadratic grid 3D (elements of Barsoum) around melts of crack and a FEM.***
- Modeling C tests K1 and K3 with a linear grid 3D with a traditional resolution but one extraction of the factors of intensity based on an energy calculation.***

***Moreover, for each modeling, various cases of loadings are studied:***

- traction (request in mode I);***
- torsion (request in mode III);***
- inflection (opening of dimensioned, closing of the other) with and without taking into account of the contact.***

*The cases of traction and torsion do not put concerned the contact.*

*Although symmetries exist in certain cases (axisymetry for case 1, symmetry planes for 2nd) representation is made in 3D to make the test generalizable under multiple loading.*

***Method of calculation used for the reference solution***

***For an axisymmetric crack in a cylinder infinite length, method of the Equations***

*Singular integrals and of the Asymptotic Developments [bib1] makes it possible to calculate the values of stress intensity factors.*

· *Cas 1: Traction and Torsion*

*Traction induces an opening in mode 1.  $K_I$  is given by the following formula:*

$$K_I = \frac{P}{F} \sqrt{\frac{I}{2\pi b}}$$

*where  $P$  is the effort applied to the higher and lower face and  $F$  a given function [Figure 2.1-a].*

*Torsion induces an opening in mode 3.  $K_{III}$  is given by the following formula:*

$$K_{III} = \frac{T}{F} \sqrt{\frac{I}{2\pi b}}$$

*where  $T$  is the moment applied to the higher and lower face and  $F$  a given function [Figure 2.1-a].*

· *Cas 2: Inflection without contact*

*The inflection induces an opening in mode 1. The value of  $K_I$  at the point of maximum opening  $A$  is given by the following formula:*

$$K_I = \frac{4M}{F} \sqrt{\frac{I}{2\pi b}}$$

*where  $M$  is the moment applied to the higher and lower face and  $F$  a given function [Figure 2.1-a].*

**With  
has**

**where  $M$  is the moment applied to the higher and lower face and  $F2$  a given function [Figure 2.1-a].**

**· Cas 3: Inflection with contact**

**There is not analytical solution with this problem. One expects on the one hand that  $K1$  is close to case without contact on the part of the crack in opening, and in addition that  $K1$  is null on the part of the crack in closing.**

***Results of modeling A***

***4.1 Values***

***tested***

*Procedure POST\_K1\_K2\_K3 makes it possible to identify the values of the stress intensity factors with a coefficient close, by two methods. We will limit the test to the results resulting from the method 1, which seem more stable. One recalls that this method calculates, for each couple of nodes in opposite around the point of the bottom of crack considered, the jump of the field of displacement squared and divides it by R [bib2]. One limits oneself to 3 or 4 couples of nodes, and one will take the maximum value like result (the most constraining value).*

#### *4.1.1 Results in the case of a loading in traction (K1) and torsion (K3)*

##### *Identification Reference*

*15/20*

**Note:**

*When one calculates the jumps of displacements along the bottom of crack (POST\_K1\_K2\_K3), it first point met on the basis of the node on the bottom is the node moved with the quarter of the element of adjacent Barsoum. However for this node with the quarter, the management of the traditional contact is not valid.*

*Indeed, the method of the active constraints with linearization with the nodes mediums implies that it displacement of the nodes mediums is worth the average of displacements of the adjacent nodes.*

*However here,*

*the node medium being moved with the quarter, this approximation is not licit.*

*As the contact is not taken into account correctly for these nodes with the quarter, it appears judicious not to estimate K1 at it, especially when there is contact. On the following nodes, the jump of displacement is quite correct and K1 is worth zero (see [Figure 6.2-b]).*

.

.

fissure considered

•  
•  
•  
False K1 if contact

Correct K1

***Appear 6.2-c: Configuration of calculation close to the bottom of crack***

*This is not quite serious in practice but when there is contact, one knows that K1 must be null.*

*Moreover, a solution consists in tracing K1\_MAX when the crack opens, and K1\_MIN when it  
firm (it is what is made on [\[Figure 6.2-b\]](#). In the case of closing, K1\_MIN is quite null since it  
is based on the values of K1 given by the jumps of displacements of the following traditional nodes  
the nodes with the quarter, which are correctly treated with regard to the contact.*

## ***Results of modeling C***

### ***8.1 Values***

#### ***tested***

*L`option CALC\_K\_G of order CALC\_G\_LOCAL\_T makes it possible to extract the values from the factors*

*of intensity of constraints by the G-théta method by using the bilinear form of G (generalization with 3D of the case already existing 2D in Code\_Aster). As for the traditional G-théta method, it is necessary to give a value for Rinf and Rsup (rays lower and higher of the torus being used as support than field théta).*

#### ***8.1.1 Results in the case of a loading in traction (K1) and torsion (K3)***

**Identification Reference****Aster****% difference**

Max (K1)

5.35 106 5.11

106 4.47

Max (K3)

11.22 106 10.52

106 6.24

The values of K1 and K3 must be identical [\[Figure 8.2-a\] for](#) all the nodes of the bottom of crack because there is an axisymmetric configuration. Here, we test the maximum of K1 and K3 for all them points of the bottom of crack.

**8.1.2 Results in the case of a loading in inflection (K1) without contact****Identification Reference****Aster****% difference**

K1 with node A

11.71 106 10.32

106 11.88

One compares the value of K1 with the reference solution only to the point of maximum opening bus it is the only analytical value available in the literature. This point is not any more one “node” but one “not” of the bottom of crack, it should then be located by its number in the list of the points of the bottom of fissure. It is the point located by NUM\_PT=11.

**8.1.3 Results in the case of a loading in inflection (K1) with contact****Identification Reference****Aster****% difference**

K1 with node A

10.32 106 9.43

106 8.57

One compares the result obtained with that obtained by Code\_Aster without taking into account of the contact (not-regression). This taking into account is carried out by the method of the active constraints.

[\[Figure 8.2-b\]](#) compares the values of  $K_I$  along the bottom of crack in the case of inflection with and without contact.

:

*V6.04.166-A Page:*

19/20

**Note:**

*It is noted that if the contact is taken into account ([see \[Figure 8.2-b\]](#)), K1 is not really no one on the segments of the bottom of crack where there is closing. That comes owing to the fact that*

*energy method of calculation of K projects the field of solution displacement on the fields singular auxiliaries of displacement of an infinitely long crack in opening. However these fields auxiliaries are not compatible with the mode of closing present.*

**9**

**Summaries of the results**

*The objectives of this test are achieved:*

.

*It is a question of validating the taking into account of the contact on the lips of the crack with elements quadratic (and of the elements of Barsoum). The results better, are compared with those obtained with a linear grid.*

.

*This test shows the interest of the method “G-theta” for calculation of the factors of intensity of constraint. This energy method has the advantage of being more general than that using the jump of displacements (POST\_K1\_K2\_K3) because it can apply to cracks of unspecified geometry, whereas POST\_K1\_K2\_K3 is restricts with the plane cracks. Of more, the method “G-theta” gives better results (compared with the analytical solution) that POST\_K1\_K2\_K3 for the same linear grid.*

.

*In addition, this test constitutes a reference and will allow the validation of the introduction of method X-FEM in Code\_Aster applied to calculations of the factors of intensity of constraints.*

## ***SSNV171 - Comparison POLY\_CFC and MONOCRYSTAL***

### ***Summary:***

***One presents here a test having for reference another model of behavior already validated in Code\_Aster, who is POLY\_CFC. The treated geometry is a cube. The goal is to test the concept MONOCRYSTAL while using a law of behavior equivalent to POLY\_CFC.***

*The goal of this modeling is the comparison between the values of the stress fields and of deformations obtained with the monocrystal into implicit and explicit as well as the comparison for two modelings of the values of the variable interns V43 which is the cumulated plastic deformation total of the monocrystal.*

***Viscoplastic SSNV172 Behaviors***  
***single-crystal***

***Summary:***

***This test makes it possible to validate the single-crystal behaviors in a uniaxial situation. Geometry treated is a cube, the stress and strain state is homogeneous. In order to test the laws as well as possible of behavior, independently of the definition of the systems of slip, one uses a system here of particular slip, nonphysical, which represents a slip in only one direction. This allows to compare two of the single-crystal viscoplastic behaviors, (with kinematic work hardening defined by a variable of recall) to the macroscopic viscoplastic behaviors of Chaboche. For the others behaviors one checks only nonthe regression of the results.***

***All these tests are carried out in only one modeling.***

***Document: V6.04.173***

***SSNV173 Bar fissured with X-FEM***

***Summary***

***The purpose of this test is to validate two aspects of elementary calculation within the framework of X-FEM [R7.02.12]:***

- *the integration of a discontinuous size thanks to a under-cutting of the element,*
- *the enrichment of the functions of form by the Heaviside function.*

*This test brings into play a parallelepipedic bar fissured on all its section, subjected to a displacement imposed, which has as a consequence the total opening of the crack and the separation of the two parts of structure.*

*The influence of the grid and the boundary conditions is also studied.*

***Problem of reference***

### ***1.1 Geometry***

***The structure is a right with low square and healthy parallelepiped. Dimensions of the bar (see [Figure 1.1-a]) are:  $LX = 5$ ,  $LY = 5$  and  $LZ = 25$ . It does not comprise any crack.***

***The crack will be introduced by functions of levels (level sets) directly into the file order using operator `DEFI_FISS_XFEM` [U4.82.08]. The crack is present in the middle of the structure by the means of its representation by 2 level sets *LSN* and *LST* (see [Figure 1.1-b]) of which them equations are as follows:***

***LSN (for the plan of crack):  $Z = LZ/2$***

***éq***

***1.1-1***

***:***

***fissure)***

***of***

## **Author (S):**

***S. GENIAUT, Key P. MASSIN***

**:**

***V6.04.173-B Page:***

**3/10**

**2**

***Modeling a: only one finite element***

**2.1**

***Characteristics of the grid***

***The structure is modelled by only one finite element of type HEXA8. The crack is thus present at centre of this element by the means of the level sets.***

**2.2**

***Boundary conditions***

***Considering that the nodes close to the crack, i.e. here the 8 nodes of the grid are enriched by ddls additional, the boundary conditions are written a little differently. That relates to the enrichment of the traditional functions of forms [R7.02.12] by the function Heaviside  $H(X)$ .***

***To impose a null displacement on the nodes of the lower face amounts writing a linear relation between the ddls. For each node, one imposes  $DCX H1X = 0$  (idem according to y and Z) where  $DCX$  is the ddl traditional and  $H1X$  the enriched ddl.***

***For the nodes of the higher face, one imposes a displacement according to Z being worth  $10^{-6}$  and no one following two other directions, i.e.  $DCX + H1X = 0$ ,  $DCY + H1Y = 0$  and  $DCZ + H1Z = 10^{-6}$ .***

**2.3 Resolution**

***analytical***

***The solution of such a problem is of course obvious. It is seen well that mechanically speaking, both***

*left the structure will be detached: the lower part will have a null displacement and the part higher an overall movement equal to imposed displacement will have (see [Figure 2.3-b]).*

*In our case, it does not occur anything according to  $X$  and  $y$ , and according to symmetries of the problem, one can*

*to study only on one vertical edge (for example that joining the noted nodes  $N1$  and  $N2$ ).*

*There are four conditions to satisfy:*

- displacement of null the  $N1$  node*
- displacement of the point lower medium Has no one*
- displacement of the node  $N2$  equal to imposed displacement, noted  $uz$*
- displacement of the point medium higher  $A+$  equal to  $uz$*

*According to the formulation, these four conditions are written respectively:*

$$dcz1 - H z1$$

$$1 = 0$$

$$1$$

$$dcz 0$$

$$0$$

$$1$$

$$1.-10 uz 2$$

$$1 (dcz1 - H z1$$

$$1 + dcz2 - H z2$$

$$1) = 0$$

$$1$$

$$2$$

$$1$$

$$H Z$$

$$1 2$$

$$1 2$$

$$1 2$$

$$1 2$$

$$0 uz 2$$

=  
=

$$\begin{aligned} &dcz2 + H z2 \\ &1 = uz \\ &2 \\ &dcz \\ &1 \ 2 \ -1 \ 2 \ 1 \ 2 \ -1 \ 2 \end{aligned}$$

$$uz \ uz \ 2$$

$$\begin{aligned} &2 \\ &1 \\ &-1 \\ &0 \\ &0 \\ &uz \ uz \ 2 \\ &1 ( \\ &1 \\ &H \ Z \end{aligned}$$

$$\begin{aligned} &dcz1 + H z1 \\ &1 + dcz2 + H z2 \\ &1) = uz \end{aligned}$$

2

*The analytical solution is then the following one: all the ddls according to X and are null there and all the ddls according to Z are worth uz/2.*

## **4**

***Modeling b: Several finite elements***

### **4.1**

***Characteristics of the grid***

*One discretizes the structure in 5 finite elements HEXA8*

*The nodes on both sides of the crack are nodes nouveau riches, therefore them three central meshes having such nodes are they also enriched.*

*Only the two extreme meshes are traditional meshes having only traditional nodes.*

*One will be able to thus impose boundary conditions on the extreme meshes in the usual manner.*

### **4.2**

***Boundary conditions***

*The boundary conditions applied represents the same phenomenon physics that for modeling A. One embeds the nodes of the face lower and one imposes a displacement of the nodes of the face higher:*

***Appear 4.1-a: Grid***

*Lower face (Nodes N1, N6, N11, N16):  $DX = 0$ ,  $DY = 0$  and  $DZ = 0$*

*Higher face (Nodes N21, N22, N23, N24):  $DX = 0$ ,  $DY = 0$  and  $DZ = u_z$ .*

*This constitutes the 1st case of loading.*

*In fact, one takes freedom to move the higher part of the structure according to the three directions, one will thus choose like 2nd case of loading:*

*Lower face (Nodes N1, N6, N11, N16):  $DX = 0$ ,  $DY = 0$  and  $DZ = 0$*

*Higher face:  $DX = ux$ ,  $DY = uy$  and  $DZ = uz$*

$$ux = 10^{-6}$$

$$uy = 2 \cdot 10^{-6}$$

$$uz = 3 \cdot 10^{-6}$$

### **4.3 Resolution analytical**

*The solution of such a problem is of course still obvious. In a way similar to [§2.3], one can to show that the solution is as follows:*

*Nodes of the lower face (stage n°0):*

$$DX = 0, DY = 0 \text{ and } DZ = 0.$$

*Nodes of the stage n°1:*

$$DX = 0, DY = 0 \text{ and } DZ = 0.$$

*Nodes of the stages n°2 and 3:*

$$DCX = ux/2, DCY = uy/2, DCZ = uz/2,$$

$$H1X = ux/2, H1Y = uy/2 \text{ and } H1Z = uz/2.$$

*Nodes of the stage n°4:*

$$DX = ux, DY = uy \text{ and } DZ = uz.$$

*Nodes of the higher face (stage n°5):*

$$DX = ux, DY = uy \text{ and } DZ = uz.$$

***Modeling C: Several elements and interfaces leaning***

**6.1**

***Characteristics of the grid and the interface***

*One considers a structure of dimensions  $LX = 5\text{ m}$ ,  $LY = 5\text{ m}$  and  $LZ = 25\text{ Mr}$ . This structure are discretized with 5 finite elements HEXA8. One is interested in a plane interface of normal*

*1*

*-*

*$N = 1$*

1

passing by point A of co-ordinates (5, 5, 5). [\[Figure 6.1-a\]](#) a zoom of the 2nd element [shows](#) where the trace of the interface is represented in red.

N9

### **Appear 6.1-a: Grid C and zoom**

The interface is characterized by the level set normal having for Cartesian equation:

$$lsn = -X + y + Z -$$

5

#### **Note:**

The parameter has a strong influence on the problem. If 0 or 1 are worth, then point A coincides with a node, and the interface passes by this node. If is nonnull, but small in front of 1, the interface will separate the element into 2 part, very different volumes. In this situation, enrichment N9 node by the Heaviside function becomes almost useless, and led to very small pivots during the factorization of the matrix of rigidity. That results in a significant loss of a number of decimals and with a false result. For  $\epsilon = 0.1$  (either point A accounting for 10% of the edge), one loses already 8 decimals (default value causing a fatal error) and for  $\epsilon = 0.05$ , one lose 10 decimals. The idea thus consists in not enriching the N9 node by the function Heaviside when such cases arise. An algorithm of detection was set up, based on the volumetric ratio for an element crossed into two. This problem makes it possible to test the good operation of the algorithm, when the parameter becomes small. In the continuation, one will take  $\epsilon = 0.02$ . This value leads to the loss of 13 decimals at the time of factorization (before the installation of a special treatment).

The algorithm will be validated if calculation proceeds normally, without loss of decimals in factorization. One will check also solution displacement in a selected node.

## ***Results of modeling C***

### ***7.1 Values***

#### ***tested***

*The good course of calculation makes it possible a priori to validate the case. Moreover, one tests the values of displacement with the N1 node of co-ordinates (0, 5, 0) as well as contact pressures (LAGS\_C). One make sure that the displacement of the N1 node is correct and that contact pressures all are null (loading of traction).*

### ***Identification Reference***

*0.00*

**Recall:**

*DCZ is the component according to Z of the traditional ddl*

*HIZ is the component according to Z of the enriched ddl*

**8**

**Summaries of the results**

*The objectives of this test are achieved:*

.

*It is a question of validating the taking into account of enrichment by the Heaviside function of traditional functions of form.*

.

*Moreover, modeling B allowed the validation of the operand LIAISON\_XFEM which allows to remove the ddls nouveau riches in excess.*

**1**

**Problem of reference**

**1.1**

**Geometry and boundary conditions**

**The element used is a tetrahedron at a point of gauss. There is thus no problem of homogeneity fields in the element.**

**The conditions of blockings and the relations linear between the nodes which should be applied are summarized**

**on [Figure 1.1-a]. Edges N0N1, N0N2 and N0N3 are length 1.**

**Taking into account the geometry of the element, conditions of blockings and relations linear, deformation is directly connected to displacements of the nodes:**

**= DX (N1)**

**xx**

**= DY (N2)**

**yy**

**= DX (N3)**

**zz**

**= DX (N2) =DY (N1)**

**xy**

**= DX (N3) =DZ (N1)**

**xz**

**= DY (N3) =DZ (N2)**

yz

*If one works with imposed deformation, it is thus enough to impose displacement on the adequate nodes.*

*If one wishes to work with imposed force, as it is the case for modeling E, it is necessary to impose them following loadings (see it [Figure 1.1-a] for the definition of the faces F1, F2, F3 and F4):*

*> 0: FX on F1 and - 3/3FX on F4,  $FX < 0$  (traction according to X)*

## **7 Modeling**

**E**

### **7.1**

#### **Characteristics of modeling**

Modeling 3D

Element MECA\_TETRA4.

### **7.2**

#### **Characteristics of the grid**

A number of nodes: 4

A number of meshes and types: 1 TETRA4

### **7.3 Functionalities**

**tested**

One tests here the law of behavior ENDO\_ORTH\_BETON in 3 cases of loading:

1) U1: Simple traction

2) U2: Compression

3) U3: Biaxial loading (traction in the direction y, compression in direction X, with one report/ratio fixes constraints:

= - 0.2

yy

xx

This case test makes it possible to check that the set of parameters chosen by the user respects the data following:

- breaking stresses in traction,
- breaking stresses in compression,
- not of swelling of the envelope of rupture for biaxial tests. That consists in checking that the maximum constraint in traction of the biaxial test is lower than the constraint of rupture in simple traction.

## 7.4

### Way of loading

With the difference in modelings A, B, C and D, it is the force, and not the displacement, which is here imposed. One uses the method of piloting of loading PRED\_ELAS, because the behavior is polishing substance. The following loadings are applied:

1) U

-

1: FX on F1,

3/3FX on F4, FX<0 (Traction)

2) U

-

2: FX on F1,

3/3FX on F4, FX>0 (Compression)

3) U

-

3: FX on F1,

3/3FX on F4, FX>0 (Compression according to axis X);

FY on F2, - 3/3FY on F4, with FY= -0,2 FX (Traction according to the axis y).

**Warning 1:** It may be that the number of steps of time is insufficient to reach the phase lenitive. The user will thus check that for calculations U1 and U2, U3 calculation being subjected to one warning additional (cf **warning 2**), it is well in the lenitive phase (reduction in the parameter of piloting). The maximum constraint in absolute value should not be attack for the last step of time. In the contrary case, it is necessary to continue calculation until the phase lenitive.

**Warning 2:** It is possible, for certain set of parameters, to observe difficulties of convergence for U3 calculation at the time of the lenitive phase. Indeed, the law of behavior ensures the existence and the unicity of the solution in imposed deformation, but not in imposed force. These problems of convergence appearing only in the lenitive phase, the user will be able to consider the greatest value of the parameter of piloting reached, equal to the greatest constraint of compression reached in absolute value, like reference to gauge K2. This is true only

xx

if there are problems of convergence. If there is no problem of convergence for U3 calculation, and that the maximum constraint in absolute value is reached for the last step of time, calculation should be continued.

## 8

### Summary of the results

The objective of the modelings presented in this document is to identify the parameters of the law ENDO\_ORTH\_BETON. Insofar as there is not empirical formula for the values of parameters to be used, the user will have to gauge his parameters step by step on the various tests proposed. The method to gauge the parameters, which is in the document [R7.01.09], can to be summarized as follows:

- choice of ALPHA: (0,85 to 0,9),
- calibration of K0, ECROB on modelings A, C or E (U1 calculation). Once these parameters gauged, it should not be modified in the phase of calibration of the other parameters,
- calibration of K1, K2 and ECROD on modelings B (or D) and E. In fact, modeling E (calculations U2 and U3) is enough. It makes it possible to check the value of the breaking stress in simple compression, and to ensure that the envelope of rupture for biaxial tests do not inflate. It is not necessary to gauge the K2 parameter in a very fine way bus it rise from a qualitative argument, and no experimental data is never available for to identify.

***Reference solution***

***2.1***

***Method of calculation used for the reference solution***

***The goal of the reference solution is analytically to calculate the value of the threshold from which creep appears.***

***Some results of nonregression on displacements with the last step of time are added to check the total rigidity of the system.***

*For the analytical calculation of the threshold one a:*

*As long as the structure remains elastic and because of the boundary conditions, the tensor of the constraints is written:*

· *For the first step of time ranging between 0 and 106 S*

*(T*

*4*

*-*

*xx) =*

*2*

*·*

*2 10 T, T in second and xx in MPa. The other components of the tensor are null.*

· *For the others not of time, = 220 MPa*

*xx*

*However one a:*

*T*

*1*

*D = U of*

*eq ()*

*S 0*

*Maybe as in this case*

*=, one obtains in an immediate way by solving D=1 the value of*

*eq*

*xx*

*time from which creep is declared: T1 = 4.08181818 106 S*

*Thus for a time equal to T1, the viscous deformations are null and D is worth 1.*

## ***Summary of the results***

*The objective of this case test is completely filled since activation of creep via the detection of threshold is very precise (about 10-8% of error). Of course, since it is about viscous phenomenon, the discretization in time plays a very important part in particular in the surrounding of the activation of the threshold.*

*In this case test a very particular care was taken to surround time when the threshold is reached in way specify to obtain satisfactory results.*

## **Boundary conditions and loadings**

*In this test, one creates a homogeneous field of drying in the structure varying linearly on one 750 days duration, initial moisture is worth 100% (condition of a sealed test-tube) and decrease gradually up to 50% with the 750<sup>ème</sup> day.*

*The degree of hydration varies linearly from 0 to 1 between the initial moment and the 28th day.*

*The temperature of reference is worth 20°C. The thermal loading corresponds to a rise in temperature varying of 20 °C and 40°C between the initial moment and the final moment.*

*The mechanical loading corresponds to an one-way compression according to the direction vertical (Z in 3D); its intensity is 12 [MPa]. The load is applied in 1s and is maintained constant during 100 days.*

### **1.4 Conditions**

#### **initial**

*The beginning of calculation is supposed moment 1. At this moment there is neither field of drying, nor forced mechanics.*

*At moment 0, one applies a field of drying corresponding to 100% of hygroscoy, a field of hydration corresponding to a null advance and a thermal field to the temperature of reference.*

### **Reference solution**

## 2.1

### **Method of calculation**

*One did not develop the analytical solution for this hydro-mechanical loading. Also, the solution from reference is obtained numerically by using the software Scilab 2.7.2. Each component of deformation is calculated separately:*

*· the deformations of endogenous withdrawal are given starting from the relation:*

-

$$Re = K$$

.

$Re$

*where the degree of hydration of material indicates*

*· the deformations of withdrawal of desiccation are given starting from the relation:*

-

$$\epsilon = K C$$

. &

$rd$

$rd$

*where  $C$  indicates the water content of material*

*· the deformations of thermal dilation are given starting from the relation:*

-

$$HT = (T - ref.$$

$T$

$)$  where  $T$  and  $ref.$

$T$

*indicate the temperature at the moment respectively*

*running and the temperature of reference of material*

*· the deformations of clean creep are calculated numerically by using one discretization identical to that established in Code\_Aster.*

*· the deformations of creep of desiccation are calculated analytically from relation:*

$1$

-

$$\epsilon =$$

$h\epsilon$

$fd$

*where  $H = F(C)$  indicates the moisture of material*

$fd$

*The results of calculation with Scilab are presented in the figure below.*

## 2

### *Reference solution*

## 2.1

### *Method of calculation*

*The analytical solution rests on the resolution of the two differential equations which control deviatoric part of the behavior (cf [R7.01.06]).*

*The deviatoric constraints are at the origin of a mechanism of slip (or mechanism of quasi dislocation) of the layers of HSC in nano-porosity. Under deviatoric constraint, creep be carried out with constant volume. In addition, the law of creep UMLV supposes the isotropy of creep deviatoric. Phénoménologiquement, the mechanism of slip comprises a contribution reversible viscoelastic of the water strongly adsorbed with the layers of HSC and a contribution irreversible viscous of interstitial water:*

***SSNV182 Block with interface in rubbing contact  
with X-FEM***

***Summary***

*The purpose of this test is to validate the taking into account of the contact on the lips of the crack, while being limited if the crack crosses the structure completely. The contact is taken into account by the method continues [bib1] adapted to the framework of method X-FEM [bib2].*

*This test brings into play a parallelepipedic block in compression. The interface the beam is represented by one level set within the framework of X-FEM. One takes into account several angular positions of the interface:  $= 0^\circ$  (the interface follows the faces of the elements) and  $= 22.5^\circ$  (the interface cuts the elements). By taking a coefficient of friction of sufficiently high Coulomb so that there is adherence, one finds the solution of same problem without interface.*

**1****Problem of reference****1.1 Geometry**

*The structure is a right at square base and healthy parallelepiped. Dimensions of the block (see [Figure 1.1-a]) are:  $LX = 5$  m,  $LY = 20$  m and  $LZ = 20$  Mr. It does not comprise any crack.*

*The interface is introduced by functions of levels (level sets) directly into the file order using operator `DEFI_FISS_XFEM` [U4.82.08]. The interface is present in the middle of the structure by the means of its representation by the level sets. The level set normal (LSN) allows to define a plane interface forming an angle with the Oxy plan by the following equation:*

$$LSN = Z - (aY + b)$$

**éq 1.1-1***LZ**LY*

*where A is the slope of the interface, that is to say has  $= -\tan()$*

*and B =*

*- has*

*.*

### **1.4**

#### ***Characteristics of the grid***

*The structure is modelled by a regular grid composed of  $5 \times 20 \times 20$  HEXA8 [Figure 1.4-a].*

**Appear 1.4-a: Grid**

*This grid is composed of linear finite elements. However, within the framework of the continuous method [bib1] with X-FEM [bib2], it is necessary to pass to a little special linear elements. These elements have linear functions of form and a quadratic mesh support. On these elements, the nodes top carry the unknown factors of displacement, and the nodes medium carry the dependent unknown factors with the contact. Moreover, when the interface follows the edge of an element, its nodes top carry too unknown factors of contact.*

**2**

**Modeling a: interfaces right**

*In this modeling, one represents a right interface, the angle is worth 0 then. The interface coincides with the faces of certain finite elements.*

**2.1 Resolution  
analytical**

*The interface being right, and the state of uniaxial pressing and normal to the interface, it does not have there possible slip. The solution of the problem is that of the same problem without interface. The constraint in the structure is:*

$UZ$   
 $= E$

***éq 2.1-1***

$ZZ$   
 $LZ$

*and the value of the contact pressure on the interface is:*

$=$

***éq 2.1-2***

$ZZ$

*With the numerical values previously introduced,  $= -5.0 Pa$ .*

## ***2.2 Functionalities tested***

### ***Orders***

***DEFI\_FISS\_XFEM CONTACT***

*This case does not require the activation of friction. Under the key word CONTACT of the operator DEFI\_FISS\_XFEM, one stipulates FROTTEMENT=' SANS' then.*

Moreover, as of the first iteration of the active constraints, one makes the assumption that the points of contact have a contacting statute. This is possible by specifying `CONTACT_INIT=' OUI'`. If not, at the end of the first iteration, the contact not being activated, the higher block returns in lower block but the two blocks did not become deformed. Their state of stresses is thus null, and it is then necessary to choose a total criterion (`RESI_GLOB_MAXI`) for the convergence of the algorithm of Newton-Raphson [bib3], criterion which is likely to be unsuited in the continuation of calculations when the contact will be activated. To avoid that, and to have a relative criterion, one needs a state of stresses not no one as of the first iteration, and thus to activate the contact as of the beginning.

The algorithm of the active constraints thus converges in an iteration.

## **Results of modeling A**

### **3.1 Values**

#### **tested**

One tests the values of the normal pressure of contact after convergence of the iterations of operator `STAT_NON_LINE` and of the loop on the active constraints. One tests all the points of contact, which corresponds to the nodes of the grid on the interface. It is checked that one finds them

well  
values determined with [§2.1].

### **Identification Reference**

**Aster** %  
**difference**  
LAGS\_C for all the nodes of  
-5.00  
-5.00  
0.00  
the interface

To test all the nodes in only once, the MIN and the MAX of the column are tested.

### **3.2 Comments**

This modeling shows the possibilities of the continuous method of contact applied to the framework X-FEM. The advantage is that the procedure of pairing is intrinsic with method X-FEM since here, there are not really surface Master and slave considering whom one has only one surface.

### **4** **Modeling b: interfaces leaning**

In this modeling, one represents a leaning interface. The angle is worth  $22.5^\circ$ , that is to say a slope has

being worth  $-1/2$ . The interface does not coincide any more with the faces of the finite elements, and cuts them now

elements. The normal with the interface is noted  $N$  and the tangent vector is noted:

0

0

$$N = 1/5, = 2/5$$

**éq 4-1**

2/5

-1/5

#### **4.1 Resolution analytical**

The interface being leaning, it is likely y to have slip. To avoid that, one forces adherence in choosing a coefficient of friction of sufficiently high Coulomb. Theoretically, it is enough to to take:

$$\mu > \tan ()$$

**éq 4.1-1**

Thus, the solution of the problem remains identical to that of the same problem without interface. The constraint in the structure is always that of [éq 2.1-1], and the value of the contact pressure on the interface is a function of normal  $N$  to the interface:

$$= N N = N N$$

*éq*  
**4.1-2**

$$Z$$

$$zz Z$$

where  $n_z$  is the component according to  $Z$  of  $N$ .

The semi-multiplier of friction is defined by:

$$R =$$

$$\mu$$

*éq* **4.1-3**

With the density of tangential stress being written as follows:

$$R =$$

*éq* **4.1-4**

$$(N)$$

From where:

$$1 N$$

$$1$$

$$=$$

$$=$$

$$Z$$

*éq*

**Results of modeling B****5.1 Values****tested**

*One tests the values of the normal pressure of contact and the semi-multiplier of friction afterwards convergence of the iterations of operator STAT\_NON\_LINE, the loop on the active constraints and loop on the thresholds of friction. All the points of contact are tested. It is pointed out that these points of contact can be of two kinds: either of the nodes top, or of the nodes medium, according to whether the interface cuts or not the elements.*

*It is checked that one finds well the values determined with [§4.1]. LAGS\_F1 corresponds to semi-multiplier of friction in direction OX (it is thus null), whereas LAGS\_F2 corresponds with the semi-multiplier of following friction.*

0.00

*To test all the points of contact in only once, the MIN and the MAX of the column are tested.*

**5.2 Comments**

*Let us specify that in this study, the key word CONTACT\_INIT = “YES” makes it possible to begin the loop on the active constraints with an assumption of statute contacting for all the points of contact. That authorizes to take a relative criterion (“RESI\_RELA\_MAX”) for the convergence of the iterations of Newton. Indeed, if one selected CONTACT\_INIT = “NOT”, at the time of the phase of prediction of Newton, it contact not being activated, the higher structure moves without becoming deformed, and that lower remain motionless. The constraints are then null and a relative criterion is not usable, only a criterion total is, whose value is left with the choice of the user. The problem is that this value can to reveal calculation (active contact thereafter....) inadequate with the loadings and the constraints then in play. Thus, it is to better provide to take a single relative criterion as of the beginning.*

*Moreover, the initial value of the threshold of friction was taken to -1011 in order to be sure that one has adherence as of the 1st iteration on the thresholds of friction.*

***SSNV183 - Creep test with the model***  
***VENDOCHAB***

***Summary:***

***Model VENDOCHAB, takes again a formulation suggested by Chaboche. It is about a coupled formulation who covers a élasto-viscoplastic law with multiplicative isotropic work hardening and kinetics of isotropic damage. This law was initially developed to predict the lifespan and cracking paddles of the turbojets and more generally to envisage the time of ruin of the structures requested with high temperatures.***

***This test of nonlinear quasi-static mechanics makes it possible to validate model VENDOCHAB in 3D in the case of a test-tube subjected to an isothermal uniaxial creep test. Stress and strain states are homogeneous in the test-tube. This test validates the explicit integration of this model. Equations of this coupled formulation are described in the booklet of reference [R5.03.15].***

***The modeling of the test-tube is carried out with an element 3D with 8 nodes (HEXA8).***

**Problem of reference**

**1.1 Geometry**

*The geometry is selected voluntarily simple, to translate a stress and strain state homogeneous, as it is the case in uniaxial creep. It is here about an element of volume represented by a cube on side 3 Misters modeling is voluminal and creep is done with imposed constraint.*

**1.2**

**Properties of material**

*The characteristics are as follows:*

Key word ELAS:

*YOUNG = 150000.0 MPa*

*NAKED = 0.30*

Key word VENDOCHAB:

*S\_VP = 0. ,*

*SEDVP1 = 0. ,*

*SEDVP2 = 0. ,*

*N\_VP = 12. ,*

*M\_VP = 9. ,*

*K\_VP = 2110. ,*

*A\_D = 3191. ,*

$R_D = 6.3,$

$K_D = 14.$

### **1.3**

#### ***Boundary conditions and loadings***

$DZ = 0$  on the lower side ( $Z=0$ )

$DY = 0$  on the left side ( $Y=0$ )

$DX = 0$  on the side postpones ( $X=0$ )

*Pressure of 200 MPa imposed on the upper surface, such as:*

$P = 0$  with  $T = 0s$

$P = 200$  MPa with  $T = 0.1s$

$P = 200$  MPa until  $T = 2.5.106s$

*This corresponds to a uniaxial creep test under a constant loading of 200 MPa.*

***SSNV184 - Triaxial compression test with the model of Hoek-Brown modified***

### ***Summary***

***This test makes it possible to validate the elastoplastic law of behavior of Hoek-Brown modified in mechanics of rocks. It is about a triaxial compression test for which calculations are carried out in pure mechanics. Three levels of containment are applied: 5 MPa, 12 MPa and 25 MPa. For reasons of symmetry, one is interested only in eighth of a sample subjected to a triaxial compression test. It is about a test of not-regression.***

***V6.04 booklet: Nonlinear statics of the voluminal structures***

***Document: V6.04.185***

***SSNV185 Fissures emerging in a plate***

***3D of width finished with X-FEM***

***Summary***

***The purpose of this test is to validate method X-FEM [bib1] on an academic case 3D, within the framework of linear elastic breaking process.***

***This test brings into play a plate 3D comprising an emerging crack plane at right bottom. Complete calculation as well as the extraction of the stress intensity factors is realized within the framework of method X-FEM. grid is healthy, the crack being represented virtually with level sets.***

***Several configurations of grid are tested and compared with the analytical solution. The same problem treated in a traditional way (with a fissured grid) is used as reference in order to compare the precise details of***

*two methods.*

## ***Problem of reference***

### ***1.1 Geometry***

***The structure is a plate 3D of dimensions  $LX = 1$  m,  $LY = 10$  m and  $LZ = 30$  m, comprising one emerging plane crack length has = 5 m, being located at middle height (see [Figure 1.1-a]).***

***If the problem is dealt with by traditional method, the crack is with a grid. On the other hand, if method X-FEM is employed, the crack is not with a grid, and the geometry is in fact a healthy plate without crack. The crack will then be introduced by functions of levels (level sets) directly in the file orders using operator `DEFI_FISS_XFEM` [U4.82.08]. Level set normal ( $LSN$  = distance to the plan of cracking) makes it possible to define the plan of crack and the level set tangent ( $LST$  = distance to the bottom of crack) makes it possible to define the position of the bottom of crack.***

***Appear 1.1-a: Geometry of the fissured plate***

***One defines the points A (1, 0, 15), B (0, 0, 15) and C (1, 3, 15) which will be used to block the rigid modes.***

***1.2***

## ***Properties of material***

***Young modulus:  $E = 205.000$  MPa (except contrary mention)***

***Poisson's ratio:  $= 0$ .***

***2***

***Modeling a: fissures with a grid (traditional case)***

***In this modeling, it crack is with a grid, and one uses the standard method of the finite elements to carry out calculation. This modeling will be used as reference and will allow the comparison with method X-FEM.***

***2.1***

***Characteristics of the grid***

***The structure is modelled by a regular grid composed of 5x30x50 HEXA8, respectively according to axes X, y, Z (see [Figure 2.1-a]). Two superimposed surfaces are the lips of fissure.***

***higher face***

***fissure***

***lower face***

***Appear 2.1-a: Fissured grid***

***2.2***

***Boundary conditions and loadings***

*Two types of loading will be studied: a loading of traction on the faces lower and higher of the structure, then a loading which consists in imposing a field of displacement in any node, identical to the asymptotic field of displacement in mode I (solution of Westergaard for an infinite medium [bib2]).*

### **2.2.1 Loading of traction**

*A pressure distributed is forced on the faces lower and higher of the structure (see [Figure 2.1-a]). The pressure is*

**6**

**$p = 10$**

**-**

**$Pa ($**

**$= p$**

**$zz$**

*)-, which makes it possible to request the crack in mode of opening I pure.*

*The rigid modes are blocked in the following way:*

**N4265**

**$DX$**

**$= 0$**

**N4265**

*• Point A is blocked according to the 3 directions:*

**$DY$**

**$= 0$**

**N4265**

**$DZ$**

**$= 0$**

*• The point B is blocked along axis OZ:*

**N3751**

**$DZ$**

**2.2.2 Loading with the asymptotic field in mode I**

The asymptotic field in pure mode I, solution of a problem of elastic rupture linear is known in an analytical way [bib2]. In the defined reference mark, this field takes the following form:

 $U = 0$ **éq 2.2.2-1** $X$  $1 +$  $R$  $U = -$  $\cos$ **éq****2.2.2-2** $y$  $(3 - 4 - \cos)$  $E$  $2$  $2$

$$I +$$

$$U =$$

$$R \sin$$

**éq**  
**2.2.2-3**

$$Z$$

$$(3 - 4 - \cos)$$

$$E$$

$$2$$

$$2$$

*This field is imposed on all the nodes of the structure by the means of formulas in the operator AFPE\_CHAR\_MECA\_F [U4.44.01]. These formulas utilize the polar co-ordinates (R,) in base local at the bottom of crack:*

$$15$$

$$R = (5 - y)$$

$$Z -$$

$$^2 + (Z -)^2$$

$$15, = \arctan$$

**éq 2.2.2-4**  
 $5 - y$

*However, it is advisable to treat separately the nodes belonging to the lips of the crack. Indeed, for the nodes of the lower lip, the formula being used to calculate the angle is not valid (it would give whereas theoretically, is worth). For the nodes of the lower lip, the value of the angle is thus not calculated by the equation [éq 2.2.2-4] but is directly put at. For nodes of the upper lip, the formula is nevertheless valid.*

## 2.3

### **Solutions of the problem**

#### **2.3.1 Loading of traction**

*The stress intensity factor in mode I is given [bib3] by:*

*has*

$$K =$$

## **2.4 Functionalities tested**

Option *CALC\_K\_G* of operator *CALC\_G\_LOCAL\_T* [U4.82.04] allows the calculation of the factors of intensity of constraints by the energy method “G-theta”. This functionality is tested with the loading n°1. This case of loading is used as a basis of comparison for method X-FEM. When one of the loads is a function or a formula (coming from *AFFE\_CHAR\_MECA\_F* [U4.44.01]), the option becomes *CALC\_K\_G\_F*. This functionality is tested with the loading n°2.

2

2  
2

*For the nodes nouveau riches by the Heaviside function, it is also necessary to carry out a calculation as a preliminary.*

*Let us consider a couple of nodes A and B, and note C+ and C the points located on the upper lips and lower of the crack, this one cutting a symmetrical element of way. One is in following configuration:*

### ***Appear 10.2-a: Heaviside enrichment***

*The nodes represented by rounds [Figure 10.2-a] carry traditional ddls has and of the ddls Heaviside h.*

*According to approximation X-FEM, the crack passing in the middle of the elements, displacements are written:*

$$U() \\ WITH = A \\ + A \text{ has} \\ H$$

$$U(B) = B \\ \text{has} - B \\ H$$

$$\text{With} \\ \text{With} \\ B \\ B$$

$$+ \\ + H \text{ has} \\ + H \text{ has} \\ U(C) = \\ +$$

$$\acute{e}q \\ 10.2-5$$

## ***13.2 Comments***

*The results are stable for any selected crown.*

*The precision of the results obtained is better than for modeling C. That proves the influence beneficial of the increase size of the zone of enrichment, with identical grid.*

*However, if it one compares with the precision of modeling B (lower than 1%) one could to be astonished not to find better results with the fixed zone. The explanation is in [bib4].*

*Indeed, on modeling B, the approximation of displacement is exactly in R on one lay down element around the bottom. On the other hand, in modeling F, the approximation is R*

*elt nouveau riches*

*on the zone of enrichment. In this case (relatively coarse grid), the approximation by one summon square roots on a wide zone is worse than the approximation by only one square root on a more restricted zone.*

*However, when one refines sufficiently the grid, precision obtained with an enrichment on a fixed zone becomes better than that obtained with an enrichment on only one layer elements.*

## *14 Summaries of the results*

*The objectives of this test are achieved:*

*.*

*To validate on a simple case the taking into account of singular enrichment in bottom of crack with method X-FEM.*

*To validate the calculation of the stress intensity factors (here only mode I) for elements X-FEM, whatever the load (fixed or function).*

*It will be retained that the use of method X-FEM makes it possible to appreciably improve the precision of calculation of KI, and that this one increases when the zone of enrichment is not restricted with one only layer of elements in bottom of crack.*

***SSNV186 LBB condition and contact rubbing with  
X-FEM***

***Summary***

***The purpose of this test is to validate the taking into account of the contact (by the method continues [bib1]) on the lips of fissure within the framework of method X-FEM [bib2], when the LBB condition [bib3] [bib4] is not respected.***

***This test brings into play a parallelepipedic block in compression. The interface the beam is represented by one level set. The interface right, is nonpenchée and crosses completely the elements.***

***Oscillations of contact pressures can appear in certain cases, in particular for structures where the interface cuts pentahedrons, under a non-uniform loading.***

***That is due to the non-observance of the LBB condition [bib3] [bib4]. This phenomenon of oscillations is comparable with that met of incompressibility [bib5]. Physically, in the case of the contact, that amounts wanting to impose the contact in too many points of the interface (overstrained), returning the system hyperstatic. To slacken it, it is necessary to restrict the space of the multipliers of Lagrange, like that is done in [bib6] for the conditions of Dirichlet with X-FEM. The algorithm proposed by Moës [bib6] to reduce the oscillations is adapted to the case 3D (algorithm version 1). This algorithm made the object of an improvement to make it more physical and more effective (algorithm version 2). One comparison of the two versions is carried out.***

***Let us note that with a grid of hexahedrons, there are no oscillations.***

***1.1 Geometry***

***The structure is a right at square base and healthy parallelepiped. Dimensions of the block are:  $LX = 5\text{ m}$ ,  $LY = 20\text{ m}$  and  $LZ = 20\text{ Mr}$ . It does not comprise any crack [Figure 1.1-a].***

***The interface is introduced by functions of levels (level sets) directly into the file of orders using operator `DEFI_FISS_XFEM` [U4.82.08]. The interface is present within the structure by the means of its representation by the level sets. The level set normal (LSN) allows to define an interface planes not-leaning which crosses the elements completely, by the equation following:***

***$$LSN = Z - 17.5$$***

*2*  
*Modeling a: hexahedrons*

*In this modeling, the grid considered comprises only hexahedrons. This modeling is used as reference for the others, because this case does not have oscillations of contact pressures. Indeed, in the case of hexahedrons cut by an interface parallel to the faces, the number of contact pressures (one by cut edge) is compatible with the discretization of the field of displacement [bib1] [bib2]. The LBB condition is then respected and there are no oscillations of contact pressures.*

*2.1*  
*Characteristics of the grid*

*The problem is invariant following axis OX. In order to limit the computing time, the grid considered here*

*comprise one element along this axis. The structure is then modelled by a grid regular composed of 1x20x20 HEXA8 to see [Figure 2.1-a].*

*Appear 2.1-a: Grid of hexahedrons*

*This grid is composed of linear finite elements. However, within the framework of the continuous method*

*[bib1] with X-FEM [bib2], it is necessary to pass to a little special linear elements. These elements have linear functions of form and a quadratic mesh support. On these elements, the nodes top carry the unknown factors of displacement, and the nodes medium carry the dependent unknown factors*

*with the contact. Moreover, when the interface follows the edge of an element, its nodes top carry too unknown factors of contact.*

## *2.2 Functionalities tested*

*One uses the diagram of integration reduced to 4 points of Gauss per facet of contact. Friction is taken into account and the contact is active as of the 1st iteration of active constraints. The algorithm aiming at restricting the space of the multipliers of Lagrange is decontaminated.*

## **12 Summaries of the results 3D**

### **12.1 Summary**

***Within the framework of method X-FEM, one showed that, without particular treatment, a structure with a grid with pentahedrons subjected to a non-uniform loading can present the strong ones***

*oscillations of contact pressures (modeling B), whereas the same structure with a grid with hexahedrons subjected to the same loading does not have such oscillations (being useful modeling A of reference).*

*One proposed two algorithms allowing to reduce these oscillations significantly. The first (modeling C) seems less precise than the second (modeling D).*

*Moreover even under uniform loading, of the oscillations can appear and it is essential to use an algorithm of reduction of the space of the multipliers of Lagrange of pressure (modeling E).*

## **12.2 Curves of comparison**

*[Figure 12.2-a] gathers the curves of contact pressures along axis OY for the first 4 modelings presented. It is noticed that the oscillations for modeling B are if strong that in certain points the value of the contact pressure becomes positive, which would like to say that there is separation of the interface. The two algorithms allow a visible reduction of oscillations, and one finds the curve of reference obtained with the grid of hexahedrons.*

### **13 Modeling F: quadrangles 2D**

***This modeling is the equivalent in 2D of modeling A (reference). This case does not present oscillations of contact pressures. Just like in modeling A, the quadrangles are half-compartments by an interface parallel to the edges, and numbers it contact pressures (one by cut edge) is compatible with the discretization of the field of displacement [bib1] [bib2]. The LBB condition is then observed and there are no oscillations of contact pressures.***

#### **13.1 Characteristics of the grid**

***The structure is then modelled by a regular grid composed of 20x20 QUAD4 (See Appear 13.1-a)].***

**Appear 13.1-a: Grid of quadrangles**

## ***13.2 Functionalities tested***

***Friction is taken into account and the contact is active as of the 1st iteration of active constraints.

## *19 Summaries of the results 2D*

### *19.1 Summary*

*It, initially, was checked that the behavior of the structure of reference (modeling*

*With) could be found in 2D (modeling F). After having observed the phenomenon of oscillations in 2D, similar to that obtained in modeling B, one tested on cases in 2D both algorithms which make it possible to reduce these oscillations in 3D.*

*The two algorithms tested in modelings G and H give, in 2 dimensions, of the results very close, and allow consequently to reduce the oscillations introduced by the grid.*

## ***19.2 Curves of comparison***

*[Figure 19.2-a] represents the curves of contact pressures along axis OX for 3 modelings in 2D presented. It is noticed that the curves representative of both algorithms overlap almost completely. The two algorithms are thus about too efficient one that the other in 2D. It make it possible nevertheless to reduce the oscillations effectively.*

*Appear 19.2-a: Comparison of contact pressures following modelings 2D*

*It is it should be noted that a refinement of grid increases obviously the precision of the results obtained.*

**1.3**

### **Boundary conditions and loadings**

The thermal shock is modelled by a heat flux of 300000 W/m<sup>2</sup>s inside the cylinder.

structure has an initial temperature of 0°C.

At the same time a centrifugal force is applied: on an interval of 15 S, the number of revolutions is increased up to 2400 rad/s, then kept constant.

. (rad/s)

2400

T (S)

15

25

After 15 S, an internal pressure is applied: the pressure increases linearly up to a value from 5.5 MPa which is reached to 20 S, then the pressure goes down to zero.

p (Mpa)

5.5

T (S)

5

10

15

20

25

Thermal calculation and mechanical calculation are carried out with 50 steps of identical times.

A quarter of the cylinder is modelled by fixing the transverse components of displacements at both cross sections of the cylinder. Moreover, the degree of translation according to the length of the cylinder is

fixed on the interior ray of the with dimensions inferior of the cylinder.

**2****Reference solution****2.1****Method of calculation used for the reference solution**

Comparison with the numerical results of a voluminal modeling with the SAMCEF software V7.0 with 50

no time (module THERNL for the calculation of the field of temperature transitory and taken again with modulate MECANL for non-linear mechanical calculation).

An implicit scheme is used for the integration of the equation of heat.

Non-linear mechanical calculation was carried out with the SAMCEF software by using a modeling

axisymmetric with 5 steps of time (geometrical nonlinear modeling (“Green”)) and one voluminal modeling (a quarter of cylinder) with 5 steps of time (modeling nonlinear geometrical (“Green”)).

**7**

### **Summary of the results**

It was checked that one obtains the same results with or without recovery, with or without modification of boundary conditions.

It should be noted that the nodal efforts that one provides to Aster are divided by 2 compared to those which

one provides to the SAMCEF software into axisymmetric.

***SSNV501 Stamping of a sheet by one  
hemispherical punch (test of Wagonner)***

***Summary:***

***This test represents a calculation of stamping of a sheet by a rigid hemispherical punch in the presence of great plastic deformations. This test is very much used in the simulation of working sheet.***

***The analyzed results are the vertical displacement of the punch according to the imposed force. They are compared with a numerical reference solution.***

***Three axisymmetric modelings are carried out. The contact blank/punch and blank/die are of the type node-mesh.***

- Modélisation a: the coefficient of friction, contact blank/punch and blank/matrix is null.***
- Modélisation b: the coefficient of friction, contact blank/punch and blank/matrix is equal to 0.15.***
- Modélisation C: modeling similar to modeling A with a finer grid for the blank.***

## **Summary of the results**

*On the figure below we present, for modeling A, the deformation of the blank, the position of the matrix and of the punch for a loading of 75kN.*

*One notes a variation compared to the references [bib1] and [bib2]. For a loading reaching 75% total specified in these references, we have:*

- for A, 7,5% of error on displacement,*
- for C, 9,7% of error on displacement.*

*For modeling B (with friction), the error with 75% of the load given by the references [bib1] and [bib2] is 6%.*

**SSNV503 - Shoe slipping on a rigid level**

**Summary:**

***This test represents a calculation of contact of a shoe slipping on a rigid level. The objective of this test is of to allow to validate in an unquestionable way calculation of the criterion of Coulomb and the good transmission of pressure.***

***Various modelings of the zone of contact tested are as follows:***

***• Modélisation A (2D): contact node-mesh, Lagrangian method for the contact and friction, play***

**geometrical.**

- **Modélisation B (2D): contact node-mesh with Lagrangian method and play defined by a function.**
- **Modélisation C (2D): contact node-mesh, method Lagrangian for the contact and penalized for friction, geometrical play.**
- **Modélisation D (2D): contact node-mesh, method penalized for the contact and friction, play geometrical.**
- **Modélisation E (3D): contact node-mesh, method Lagrangian for the contact and penalized for friction, geometrical play.**
- **Modélisation F (3D): contact node-mesh, method Lagrangian for the contact and penalized for friction, play defined by a function.**
- **Modélisation G (3D): contact node-mesh, method penalized for the contact and friction, play geometrical.**
- **Modélisation H (2D): contact node-mesh, method continues for the contact and friction, play geometrical.**

## 12.2 Remarks

- The play is defined in this case in a geometrical way, the results are identical to those found in preceding modeling.
- The pressures normal and tangential on the level of the zone of contact are checked while testing total force of contact in the normal and tangential direction:

***Document: V6.04.504***

***SSNV504 - Extrusion of a piece***

***Summary:***

***This test simulates the extrusion (without friction) of a piece, case frequently encountered in the industrial studies of working. The interest of this test is mainly to validate the “passage” of geometrical singularities (acute angles and blunt) and to test the taking into account of two zones of contact (contact multi-zones).***

***Modelings selected are as follows:***

.  
***Modeling A (AXIS):***

***CONTACT node nets, associated with meshes SEG2,***

.  
***Modeling B (3D):***

***CONTACT node nets, associated with meshes QUAD4,***

.  
***Modeling C (AXIS): CONTACT node nets SLIDE, associated with meshes SEG2,***

.  
***Modeling D (AXIS): CONTACT, method CONTINUES associated with meshes SEG2,***

.  
***Modeling E (AXIS):***

***CONTACT node nets SLIDE, associated with meshes SEG3,***

.  
***Modeling F (3D):***

***CONTACT node nets SLIDE, associated with meshes QUAD4,***

**Modeling G (3D):**

**CONTACT node nets SLIDE, associated with meshes QUAD8,**

**Modeling H (2D):**

**CONTACT, method CONTINUES associated with SEG3**

**Modelings with SLIDE make it possible to maintain the contact throughout extrusion, in way mathematics. The result is physically close to modeling without slide, since it is about one extrusion without friction.**

## **6.2 Remarks**

.

*Calculation is carried out by imposing a displacement on the back face of the piece (MN).  
displacement is imposed in the following way:*

-

*of*

*0.mm with*

*5.mm in 5 steps*

-  
of  
5.mm with  
15.mm in 10 steps  
-  
of  
5.mm with  
20.mm in 5 steps  
-  
of  
20.mm with  
50.mm in 5 steps  
-  
of  
50.mm with  
70.mm in 10 steps  
-  
of  
70.mm with  
140.mm in 35 steps  
-  
of  
140. mm with  
155.mm in 15 step  
.

Although the data file passes without problem in linear statics (MECA\_STATIQUE), them calculations do not converge with the key words by defect used for convergence in STAT\_NON\_LINE, because the default value of RESI\_GLOB\_RELA = 1.E-6 is too constraining (forces to which the piece is subjected being at the beginning relatively weak). To mitigate it problem, it is necessary to use the key word RESI\_GLOB\_MAXI = 1.E-6.

## **8.2 Remarks**

.

*Calculation is carried out by imposing a displacement on the back face of the piece (MN).  
displacement is imposed in the following way:*

-

*of*

*0.mm with*

*5.mm in 5 steps*

-

*of*

*5.mm with*

*20.mm in 5 steps*

-

*of*

*20.mm with*

*50.mm in 5 steps*

-

*of*

*50.mm with*

*70.mm in 5 steps*

-

*of*

*70.mm with*

*140.mm in 5 steps*

.

*Although the data file passes without problem in linear statics (MECA\_STATIQUE), them  
calculations do not converge with the key words by defect used for convergence in  
STAT\_NON\_LINE, because the default value of RESI\_GLOB\_RELA = 1.E-6 is too constraining  
(forces to which the piece is subjected being at the beginning relatively weak). To mitigate it  
problem, it is necessary to use the key word RESI\_GLOB\_MAXI = 1.E-6.*

**17 Modeling  
H**

**17.1 Characteristics of modeling**

**Modeling with quadratic elements of contact (SEG3) by the method CONTINUES. It**

*case-test presents phenomena of flip-flop (oscillations of the statute of the contact related to difficulties of zero numerical), solved here by an internal test on the maximum number of flip-flop (transparent with the user, and fixed at 15), i.e. the maximum number of changes of statute of the contact. One message of alarm indicates to the user that the maximum number of changes of statute (15) was reached.*

.

***Although the data file passes without problem in linear statics (MECA\_STATIQUE), them  
calculations do not converge with the key words by defect used for convergence in  
STAT\_NON\_LINE, because the default value of RESI\_GLOB\_RELA = 1.E-6 is too constraining***

*(forces to which the piece is subjected being at the beginning relatively weak). To mitigate it problem, it is necessary to use the key word **RESI\_GLOB\_MAXI = 1.E-6**.*

*20/20*

## *19 Summary of the results*

*Two modelings (Axisymmetric and 3D) pass without problem. Convergence is fast.  
The results between modeling AXIS and modeling 3D are similar.*

*In the same way, the methods of the CONSTRAINTS and CONTINUOUS also give results satisfactory. On this example, the method CONTINUES seems to converge more quickly than that CONSTRAINTS, in particular in 3D with SLIDE.*

*The particular case of the contact slide is attached to this case-test: modeling C is then taken like reference. By the method CONTINUES, one obtains solutions close to these values of reference, with generally a lower iteration count.*

*On the figure above we present the position of the piece for a displacement of the face postpones piece of 20, 70, 155 mm*

*20mm 70mm 155mm*

*This test made it possible to validate:*

*.*

*the “passage” of geometrical singularities (acute angles and blunt),*  
.  
*the taking into account of two zones of contact (contact multi-zones),*  
.  
*the modeling of a contact-slide.*

## ***SSNV505 - Contact of 2 beams into large displacements***

### ***Summary:***

***This test represents a calculation of contact without friction between two beams in great displacements subjected to a specific displacement. Initially the beams are not in contact, it occurs for a level of loading given and then the two beams slip one on the other.***

***The analyzed result is the normal reaction of contact according to displacement. Results obtained with various modelings are compared between them.***

***Modeling a: the structure is modelled with elements of COQUE\_3D associated with a mesh QUAD9, with the FORCED method.***

***Modeling b: the structure is modelled in 3D plane deformations using elements HEXA8, with the FORCED method.***

***Modeling C: the structure is modelled in 2D plane deformations using elements QUAD4, with the FORCED method.***

***Modeling D: the structure is modelled in 3D plane deformations using elements HEXA8, with the method CONTINUES.***

***Modeling E: the structure is modelled in 2D plane deformations using elements QUAD4, with the method CONTINUES.***

***Modeling F: the structure is modelled in 3D using elements of beam POU\_D\_E associated with meshes SEG2, with the methods LAGRANGIAN and CONTINUOUS. This modeling is distinguished others, in what it is carried out in small transformations, while all the others are carried out in great transformations.***

***Modeling G: the structure is modelled in 3D using elements of beam POU\_D\_E associated with meshes SEG2, with the LAGRANGIAN method with friction. This modeling validates possibility of taking into account the ray of the section of beam like initial play.***

## ***13 Modeling***

### ***F***

#### ***13.1 Characteristics of modeling***

***One carries out here a modeling using elements beam in 3D. Deformations being plane in the plan (DX, DY), one imposes  $DZ = 0$  on the model 3D. The goal of this case-test is to compare deformation of the beams with a formulation in small rotations with that obtained with the large ones rotations. The first model is of course abusive (forgery) compared to the second (true), but allows to illustrate the difference of the results obtained in one or the other case. The true motivation of this case test is however of exhiber an example of validation of the contact between beams with the method continue for the preliminary stage of the small transformations. The test will be enriched soon of a modeling in great rotations, more delicate to implement.***

## **14 Results of modeling F**

### **14.1 Values**

#### **tested**

*One tests the reaction to the displacement imposed on the beam. To obtain it, one calculates the reactions to embeddings in A and B. the percentage of difference indicates the difference between this modeling and equivalent modeling with the LAGRANGIAN method.*

*On the curve of bottom, one represented the force at the point B (embedding of the higher beam) in function of the evolution of the loading. One compares the methods Lagrangian and continues with solution obtained in great rotations. It appears that the two methods give results almost identical, but that the latter differ notably from those obtained into large rotations. This point is rather logical, since within the framework of small rotations where calculations were carried out, one neglects the terms of deformation of the second order, which as one notes it are not negligible in great rotations.*

## **2**

### **Reference solution**

#### **2.1**

##### **Method of calculation used for the reference solution**

**The results of reference result from the book quoted below [bib1].**

**$p_m = 3 \sigma_0$  with  $p_m$  the contact pressure (page 171).**

**$R_{johnson} = p_m$  has  $= 3 \sigma_0 A$  if  $A$  is the surface of contact.**

**However in perfect plasticity  $= 0,368 \sigma_0 A^2 / R$  according to the analysis of Richmond (page 200)**

**Finally, one obtains:**

**$R_{johnson} = 3 R \sigma_0 / 0,368$**

**$R_{johnson}$ : Normal reaction of contact of the solid mass on the sphere**

**$R$ : Ray of the sphere**

**$\delta$ : Displacement of the top of the solid mass**

**$\sigma_0$ : Yield stress of the solid mass**

**This result is valid under the following assumptions:**

**axisymmetric problem,**

**perfectly plastic material (coefficient 0,368 results from this assumption)**

**small deformations**

**rigid sphere.**

#### **2.2**

##### **Results of reference**

**The results of reference are obtained starting from the preceding formula. It is valid for complete model in 3D.**

## **Note:**

*In our study,  $R_{\text{Johnson}}$  depends only on displacement, one can write the relation under the following form thanks to the facts of the case:  $R_{\text{Johnson}} = 640.270$  with  $R_{\text{Johnson}}$  in newton and in millimetre. is directly connected to the moment of calculation.*

*The value of the normal resultant of contact coming from ASTER is given on a district of 1 radian of opening in axisymmetric 2D and on a district of  $\pi/2$  for the model 3D (by symmetry, it is enough to model the quarter of the problem).*

*Thus, the values of reference are:*

*in axisymmetric 2D:  $R_{\text{ref}} = R_{\text{Johnson}}/2 = 101902,1$*

*in 3D*

*:  $R_{\text{ref}} = R_{\text{Johnson}}/4 = 160067,5$*

## 11 Modeling

**E**

### 11.1 Characteristics of modeling

*The symmetry of revolution of the problem allows an axisymmetric modeling: The block is represented by the cut of its half and the sphere is represented by its surface potentially in contact, they are with a grid with axisymmetric elements 2D.*

*A contact of the node-mesh type is defined between the two structures.*

*A loading in imposed displacement is applied to the higher part of the sphere rigidified by a high Young modulus.*

### ***Boundary condition:***

.  
*symmetry of revolution: the nodes located on the axis Y (group of nodes “LB” and “LS”) are blocked according to direction X ( $DX = 0$ ),*

.  
*embedding of the base: the nodes of group “PLANX” are blocked according to directions X and Y ( $DX = DY = 0$ ),*

.  
*the rigid movements of body are removed by imposing a connection following there enters it node E pertaining to the sphere and the node D pertaining to the solid mass.*

### ***Loadings:***

*An imposed displacement is applied to the higher part of the sphere (group of nodes “NDPL”) according to the direction Y: Loading from 0 to 100. mm*

## **13 Modeling**

**F**

### **13.1 Characteristics of modeling**

*The symmetry of the problem makes it possible to represent in 3D only one quarter of the model: the sphere and the block*

*are represented respectively by the surface of contact of the sphere and a quarter of cylinder, with a grid*

*with solid elements 3D CUB8.*

*A contact node-mesh is defined between the sphere and the block.*

*A loading in imposed displacement is applied to all the surface of the sphere rigidified by conditions kinematics.*

**Boundary condition:**

.

**Conditions of symmetry:**

*nodes located in plan (O, y, Z) (group of nodes “SBYZ”) are blocked according to direction X ( $DX = 0$ ),*

*nodes located in the plan (O, X, y) (group of nodes “SBXY”) are blocked according to direction Z ( $DZ = 0$ ),*

*the nodes of the sphere (group of nodes “SPHSUP”) are blocked according to directions X and Z ( $DX = DZ = 0$ )*

.

*Embedding of the base: the nodes of the group “BASES” (plane  $Y=0$ .) are blocked according to directions X, Y, and Z ( $DX = DY = DZ = 0$ ).*

.

*The rigid movements of body are removed by imposing a connection following there enters it node E pertaining to the sphere and the node S pertaining to the solid mass.*

**Loadings:**

*An imposed displacement is applied to all surface representing the sphere (group of nodes “SPHSUP”) according to the direction Y: Loading from 0 to 100. mm*

### ***14.2 Remarks***

***The results are less precise than those resulting from modelings 2D. The grid in 3D makes lose it exact character of the axisymmetric case. Moreover, for savings of time of calculation and space memory, the grid 3D is refined less than that in 2D.***

**Author (S):**

**P. MASSIN, Key Mr. KHAM**

**:**

**V6.04.506-B Page:**

**16/16**

**15 Summary of the results**

**The results obtained are good. However, a more important variation enters the reference and the results**

**3D exists. It is possible to fill it by refining even more the grid but it should be paid in place memory and in computing times.**

**The size of the elements is very important. If they are too large, one can see appearing on the curve reaction according to the displacement of the “waves” (loss of linearity of this curve). Each “vague” corresponds to the setting in contact of an element. Moreover, if the grid is not sufficiently refined, the reaction given by Aster moves away appreciably from that of reference.**

**To model only the sphere by its surface of contact rigidified by conditions kinematics a saving of time allows.**

**SSNS100 - Nonlinear behavior of a tablecloth  
reinforcements under thermal loading**

**Summary:**

**A tablecloth of reinforcements not offset compared to the layer average and embedded on its four  
sides east**

**subjected to a thermal loading. The orientations of the reinforcements are confused with the axes (X,  
Y) of  
total reference mark.**

**The principal interest of this test is to validate the numerical integration of the models of behavior  
elastoplastic GRILLE\_ISOT\_LINE, GRILLE\_CINE\_LINE and GRILLE\_PINTO\_MEN of a  
tablecloth of reinforcements**

*associated the finite element GRID (orthotropic plate with offsetting compared to the datum-line), in the algorithm general STAT\_NON\_LINE.*

*In order to obtain reference solutions, analytical solutions were established for both elastoplastic behaviours with linear and kinematic work hardening isotropic linear. The behavior of Pinto-Menegotto is validated by nonregression of the numerical results obtained with Aster in version 5-3*

*(cf [§1.3.3]).*

***SSNS102 Buckling of a cylindrical hull with stiffener***

***Summary:***

***This test of nonlinear quasi-static mechanics makes it possible to validate elements SHB8 into nonlinear geometrical, with or without taking into account of the following pressures and buckling of Euler. He shows them capacities of this element to deal with problems of thin hulls with stiffener.***

***SSNS501 - Great displacements of a panel  
cylindrical simply supported***

***Summary:***

***This test represents a calculation of stability of a cylindrical panel simply supported subjected to an***

*effort*

*concentrate in its center. The behavior of the panel changes completely and shows points clearly of return in load and displacement “snap-through/snap-back”. In this case a piloting in displacement diverge and a piloting in length of arc must be selected.*

*It makes it possible to validate modeling finite elements COQUE\_3D with meshes TRIA7 and QUAD9 in geometrical non-linear quasi-static field in the presence of strong instabilities.*

*Displacements and the critical load are compared with a numerical reference solution.*

## **4.2 Remarks**

*The strategy of calculation used breaks up into two stages:*

*.*

*calculation in loading imposed to  $P = 582.N$  correspondent on 97% of the critical load,*

*.*

*calculation in “imposed displacement”: then, one imposes a displacement imposed while using technique length of arc imposed on all the structure (option LONG\_ARC in STAT\_NON\_LINE).*

*The use of the technique length of arc makes difficult the definition of the value of reference to to introduce into order TEST\_RESU, since these values cannot be imposed. For to define the values of reference, we sought the values of the closest possible DZ those listed in the table of [§2.2] and we deferred the values of the parameter of piloting that one was to obtain for the values of DZ in question.*

:

*V6.05.501-A Page:*

9/10

*The results between the two loads limit 1 and 4 are qualitatively correct. They well are detected points limit 2 and 3. Quantitatively the values of displacements for these points are good with less than 1% for the point limits 2 and to less than 5% for the point limits 3. On the level of the loads corresponding, the load at the point limits 2 is very strongly underestimated (about 70%) and that at the point limits 3 strongly over-estimated (about 20%).*

*Whatever the mesh, the behavior pre-buckling is correctly evaluated. Pace in postbuckling makes it possible to determine displacements at the points correctly limit 2 and 3. loads obtained are further away from the reference solution. From the point limits 4, one find a good agreement between the reference and our solution.*

*The coefficient of correction of transverse shearing A\_CIS was put at 0.833, corresponding to thick hulls. The value (2500=106xH/L) which should have been taken into account does not allow to carry out calculations, because of a bad conditioning of the matrices of rigidity.*

**Reference solution**

2.1

**Method of calculation used for the reference solution**

*To refer to the document [V7.90.03] to have the complete analytical solutions.*

*The analytical results of reference are:*

.

*displacements and rotations,*

.

*axial stress, generalized efforts (in theory of hulls),*

*in skins internal and external on the sections AB and CD.*

*In axisymmetric 2D, the complete solutions given in [V7.90.03] are such as  $r_z = 0$  where R and Z are the directions radial and axial cylinder, respectively. For the loadings of rotation uniform and of thermal dilation, the boundary conditions are selected so that them solutions do not depend on Z (there is in particular  $z_z = 0$ ).*

*For the hulls, with boundary conditions equivalent, rotation around the axis orthoradial is null for the loadings of uniform rotation and thermal dilation, which is not the case of the loading of gravity where rotation is constant (the cylinder formats then conical). On the other hand in all the cases, the transverse distortion is null; thus theories of Coil-Kirchhoff and those of Hencky-Mindlin provide the same reference solution.*

## 23 Summary of the results

*The very good results obtained for modelings A and B are explained by the fact why the solutions of reference belong to the space generated by the selected finite elements. Only remain them numerical rounding errors.*

*Satisfactory results were obtained for modelings of plates and hulls in space C, D, E, F, G, H, I and J. For these last, a chained thermoelastic calculation was carried out. The results with modeling DKT (E, F, G, H, I and J) show that the elements quadrangle have a better behavior than the elements triangle. It is necessary to have a discretization sufficient fine with these plane elements in order to be able to model the geometry correctly circular of the cylindrical hull. Indeed, to discretize the geometry of the cylinder by plane facets or parabolic is not in conformity and induces a parasitic inflection which decreases with the smoothness of grid.*

***Thus a multiplication of the number of elements by two on the height of the structure makes fall the maximum error relating of 5,48% (case presented here) to 2,8%. Results with modeling COQUE\_3D (C and D) are very good except for gravity with the element triangle.***

## ***HPLA101 - Thermoelastic hollow roll. Derived compared to a variation from field***

### ***Summary***

*The purpose of this test is to test calculations of derived from the temperature, displacements and the constraints by report/ratio with a variation of field (variation of the ray interns tube), under thermal dilation.*

*The analytical solution of reference for the thermomechanical fields is described in the document [V7.90.03]. The derivative are calculated by Mathematica. One has the results for modeling following:*

*.  
axisymmetric 2D: isoparametric finite elements axisymmetric QUAD8.*

*In the case of axisymmetric calculations, to obtain the total rate of refund, it is necessary to divide it rate of refund obtained with ASTER by  $R_{fissure}$  = has (cf Reference material [R7.02.01] - page18).*

**\*\* Values obtained with the formula of IRWIN in plane deformations, by supposing that  $K_{II} = 0$ , and by taking  $G$  calculated by ASTER, which does not allow the automatic calculation of  $KI$  in axisymmetric.**

## 4.2 Remarks

*To calculate  $G_{ref}$ , one uses the formulas of IRWIN in plane deformations:*

1 - 2

$G$

=

$K_1^2 + K_2^2$

*ref.*  
 (  
 , *K*  
*I*  
*II*  
 )  
*E*  
*II* = 0

*The raised maximum change is 30% on  $G$  ( $Fo = 1$ ), of 14% on  $KI$  ( $Fo = 1$ ).*

*The maximum relative variation on the temperature in bottom of crack, compared to the analytical solution (summoned on 900 terms), is lower A 1%.*

*The maximum relative variation on  $zz$  in the bar before cracking, compared to the analytical solution summoned on 900 terms, with the site of the later bottom of crack, is lower than 0,5%.*

*With ASTER, in axisymmetric mode, the stress field obtained is following form:*

*SIXX*  
*SIYY*  
*SIZZ*  
*SIXY*

*and the associated constraints are:*

*SIRR SIZZ SITT SIRZ*

*To calculate the values of reference, we use the curve in Log/Log (page 5). Precision with reading of the values not being very good, we can estimate that the results on the rate of restitution of energy  $G$  are not too far away from the reference.*

*It should be noted that the rate of refund of energy  $G$  is invariable on the crowns of calculation.*

***Summary of the results***

***With regard to the bar not fissured, the Aster results in temperature and constraint are very close relations of the reference (less than 1% maximum for the temperature and less than 0,5% maximum for the constraints). On the other hand, for the rate of refund of energy, the Aster results are moved away from the reference since we raise a maximum change of 30% for  $FO = 0,001$ , with one precision announced of 5% on the reference solution.***

## ***Summary of the results***

- ***The calculation of K and G into axisymmetric in the presence of a stationary thermal loading, gives good results since the maximum change for G is 1,75% (out first crown) for  $\alpha = 0,4$ .***
- ***We check that the results of K and G for  $\alpha = 0,01$  are better than for  $\alpha = 0,4$ .***

## ***HPLP100 - Calculation of the rate of refund of energy of a plate fissured in thermoelasticity***

### ***Summary***

***It is about a test in thermoelasticity for a two-dimensional problem. A rectangular plate is considered fissured and one places oneself on the assumption of the plane deformations.***

***In modeling A, the rate of refund of energy is calculated in postprocessing by two methods different:***

- traditional calculation by the method theta,***
- calculation by the formula of IRWIN starting from the coefficients of intensity of constraints KI and KII.***

***These two calculations are carried out on 4 different crowns of integration. Their interest is to compare them***

***values of G and G (IRWIN) compared to the reference solution and to test the invariance of calculations by report/ratio with the various crowns of integration.***

***As for modeling B, it is about a functional and data-processing test of calculation of derived from the rate from***

***traditional restitution of energy compared to a variation of field (controlled by a function theta particular). One uses loadings which for the majority are analytical and which intervene only in post-treatment of the calculation of mechanics.***

***The architecture of the test makes it possible to simulate a finished difference, one can thus distinguish in term from***

***data-processing not-regression, possible external modifications impacting the direct problem and/or its derived.***

***From a more anecdotic point of view, one can take as a starting point the the sequences of order CREA\_CHAMP***

***used in this modeling to build analytical fields and to relocate a grid***

***Appear 5.1-a: Derived from G (F) compared to a variation of field controlled by S***

***After having built the models Mo and moth in modeling “D\_PLAN” and the field theta sensitivity S (thetas), one affects thermal loadings of temperatures type imposed on the edges right and left of the part, for then, to carry out thermal calculation itself. This last use thetas, provided via the key word SENSITIVITY, to calculate the field of temperature and its Lagrangian derivative.***

***Before carrying out thermoelastic calculation one affects the mechanical loadings. The activation of operator MECA\_STATIQUE having been made with the key word SENSITIVITY, one enriches the result by***

***the Lagrangian derivative of displacements.***

***One adds thereafter analytical loadings which intervene only in postprocessing of calculation of mechanics. They make it possible to calculate two values of G, one with a force of gravity,***

***an internal force and a field of initial deformation (G1), the other with a stress field initial (G2). The first calculation is carried out in small deformations, the second in deformations of Green-Lagrange. The crown of calculation is defined by a call to CALC\_THETA with the option THETA\_2D.***

***These tests, purely data-processing and functional, have only little interest from a point of view***

*mechanics because the majority of the loadings do not check an equation with balance.*

### ***6.2 Remarks***

*These numerical values vary if the parameters of the functions theta are modified because one uses mechanical loadings in postprocessing of thermoelastic calculation. They thus do not respect of equation to balance. By using only loadings intervening during all the process these instabilities are reduced considerably, while remaining about the percent.*

## **7 Summaries of the results**

*At the time of the first modeling, the variation with the values of reference is 6 to 7%. Validation independent of the breaking process batch should bring brief replies on the validity G in thermoelasticity.*

*The second modeling carrying out of the tests of functional and data-processing not-regression of calculation of derived from G compared to a variation of field, its results must be scrupulously respected, from where very severe criteria of tolerance.*

***HPLP101 - Plate fissured in thermoelasticity  
(plane constraints)***

***Summary:***

***This test results from the validation independent of Code\_Aster in breaking process (reference resulting from***

***Murakami: Mura11-17). It makes it possible to validate the operators of breaking process for a problem***

***two-dimensional (assumption of the plane constraints) in isotropic linear thermoelasticity.***

***This test includes/understands the first modeling in plane constraints in which are calculated:***

•  
*the rate of refund of energy  $G$  (traditional calculation by the method  $\theta$ ),*  
•  
*coefficients of intensity of constraints  $KI$  and  $KII$ .*

*These two calculations are carried out on 6 different crowns of integration.*

*The interest of the test is to compare the values of  $G$  and  $KII$  compared to the reference solution and to test  
the invariance of calculations compared to the various crowns of integration.*

*The second modeling makes it possible to calculate the derivative of  $G$  compared to the Young modulus and one  
loading in voluminal forces and to compare them with an analytical solution.*

## 4.2 Remarks

*In the reference, the author supposes that  $KI = 0$ , but it does not check it a posteriori. With the sights of deformations resulting from ASTER, coefficient  $KI$  is different from zero, but there remains very weak by report/ratio with  $KII$  (the crack slips more than it does not open).*

*With regard to the rate of refund of energy  $G$ , if we suppose that  $KI = 0$ , we draw value of reference starting from the formula of IRWIN in plane constraints:*

$G$

$ref. = (1 E)$   
 $2$

***V7.02.310 document***

***HPLP310 - Biblio\_35 Fissures radial intern in one  
thick cylinder under pressure and loading  
thermics***

***Summary:***

***This test results from the validation independent of version 3 in breaking process.***

***It is about a two-dimensional test in statics in which one models nonthe linearity of contact due to  
refermeture partial of the crack.***

***The behavior of the structure is thermoelastic linear isotropic.***

***The case test includes/understands only one plane modeling 2D for which one studies the influence of  
the load factor  
mechanics.***

***V7.02.310-A Page:***

***3/12***

***Loadings***

***Loading n° 1: radial traction  $r_r(r_2) = 0$  on the external face; this produced mechanical loading the same KI as an internal pressure acting simultaneously on the internal ray  $r_1$  and on the lips of the crack, without taking into account of nonthe linearity of contact.***

***Loading n° 2: thermal loading are equivalent to an autofrettage defined as follows:***

**4**  
**2 1-**

**0**  
**(**  
**)**  
**T = T +**  
**.**  
**· ln**  
**1**  
**3**  
**E**

**R**  
**T**  
**1**  
**(T - T**

**1**  
**)**  
**R**  
**T = T -**  
**· ln**  
**R R**  
**1**

**1**  
**R**  
**1**  
**ln**

**R**  
**1**  
**T = T**  
**R r2**

*In these formulas, the maximum ray of the zone indicates having undergone autofrettage, T1 the temperature with the ray r1 and T the temperature with the ray R = in the thick tube not fissured. In the application noted here, one takes = r2, which*

*corresponds to the autofrettage of the totality of the section of the thick tube, and one does not take into account nonthe linearity of contact. One awaits one  $K$  negative for positive temperatures (setting in compression of the tube not fissured).*

*Loading  $n^{\circ} 3$ : linear combination loading  $n^{\circ} 2 + *$  loading  $n^{\circ} 1$ , (T!) indicating the mechanical load factor; one takes here into account nonthe linearity of contact, which supposes an incremental application of the mechanical load.*

***HPLP311 - Murakami 11.17 Fissures in the center of one rectangular thin section making obstacle with one uniform heat flow in isotropic medium***

***Summary:***

***It is about an isotropic linear thermoelastic calculation static.***

***It is a basic test in plane 2D for a stationary thermal loading calculated by finite elements on even grid with an isotropic material in mode II.***

***Objective:***

- basic test in plane 2D, for a stationary thermal loading calculated by finite elements on even grid, with isotropic material, in mode II,***
- validation of the calculation of  $K_{II}$ ,***
- variability of  $G$  according to the topology (sectors, crowns) of the radiant grid. Checking invariance of the results in breaking process, at an end of crack, compared to grid of the other end of the same crack.***

***Calculation is tested on a complete grid and a half-grid. Parameters  $L/W$  and  $2A/W$  being fixed.***

***One measures a relative variation on  $K_{II}$ , the precision is nevertheless badly defined.***

**HPLV101 - Homogenisation of a material**

**homogeneous**

**Summary:**

This test tests, in a commonplace situation where the material is homogeneous, the thermal resolution of the problems

and mechanics stationary, with loadings corresponding to a variation in temperature and to one imposed deformation, close to those corresponding to the elementary problems of the method of periodic homogenisation.

3/8

2

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

· In thermics: the stationary thermal problem is solved:

-

1

$T.K. =$

·

$\mathbf{G} \mathbf{K}, \mathbf{V},$  with  $\mathbf{G}$

=

0

0

**Note:**

*The boundary conditions chosen here are not those necessary to the method*

of homogenisation: one would find  $T$  indeed  $= 0$  everywhere.

The solution is then (checking the conditions defined in [§1.3]):  $T(X, y, Z) = X$

1

1

The potential energy is then with balance:  $W_{HT} =$

$T$

$\cdot \mathbf{K} \cdot T$

$=$

here

2

-

2

· In mechanics: one solves the problem of elastostatic:

$(\mathbf{U}) \cdot \mathbf{A} \cdot (\mathbf{v}) = E \cdot A \cdot (\mathbf{v}), \mathbf{v}$

$W$

,

for the cases:

loading 3D

loading 3D

loading 2D

membrane

of inflection

plane constraints

**HPLV102 - Thermoelastic calculation of G in medium**

**infinite for a circular crack**

## **Summary**

It is about a test of breaking process into thermomechanical for an axisymmetric problem. One consider a circular crack plunged in a presumedly infinite medium. One imposes a uniform temperature on

lips of the crack. This test makes it possible to calculate the rate of refund of energy G.

The interest of the test is the stability of G according to various crowns and the comparison with an analytical solution.

This test contains a modeling into axisymmetric.

The variations of the calculation of G on various crowns compared to the reference solution do not exceed 1,5%.

## 4.2 Notice

The value of reference is  $G = 5.945 \cdot 10^{-7} \text{ J/m}^2$

It is given per unit of area of extension of the crack, therefore for  $A = 5$  and taking into account *has*

symmetry of the grid, it is necessary to compare the result of *Aster* with:  $G$

$= G$

*Aster*

$\times$

$= 1.4778 \cdot 10^{-6}$ , because  $G$

$2$

in *Aster* to a surface of extension of 1 radian corresponds.

$R_{sup}=0.6$ .

Crown 4:

$R_{inf}=0.07$

$R_{sup}=0.6$

The supports of the local field correspond to the first three crowns of the total field.

## 4.2 Remarks

.

The value of reference is the value of the rate of refund of energy room:  $Gréf = 5.66 \cdot 10^{-8} \text{ J/m}^2$ . The total rate of refund of energy provided by Code\_Aster is:

2 A

G

= G

Aster

réf  $\times$

, since by reason of symmetry one models only one quarter of the plan of

8

fissure and only one lip.

.

The results of G local are not given that for the points A and B respectively located on one symmetry plane and face of crack. Results concerning the point B (medium of face) reveal a variation from approximately 3% compared to the result of reference. Results concerning point A are worse (the variation ranges between 3% and 13.5%), which is a report usual for the estimate of G local for the points located on a symmetry plane.

2

**Reference solution**

2.1

**Method of calculation used for the reference solution****The solution is analytical.****C****B****D****M****With****The thermal loading is equivalent to a loading defined by a uniform distribution of moments on the edges such as it appears on the figure.** **$T - T$**  **$E \times e^3$** **S****I** **$\times (I + )$** **The value of these moments per unit of length is equal to:  $M =$**  **$\times$** **.****E****(** **$12 I - 2 )$**  **$E \times e^2$** **That is to say:  $M = (T - T$** **S** **$I) \times$** **. This led to a uniform distribution of  $M$  in the plate** **$12(I - )$** **.**

2.2

**Results of reference****There are thus  $M = 2380.95238$  NR; the plate being turned of an angle  $= 53^\circ.1301$ , one has components whose absolute value is:  $M \times \cos = 1428.5715$  NR and  $M \times \sin = 1904.76184$  NR.****The reactions are defined by a distribution of moments equal to the preceding one in absolute value**

*and of contrary sign.*

*The meshes are squares of which the length is equal to 0.05 m, therefore the moments in each node to  $M1 = M \cos X 0.05 = 71.42857 \text{ N.m}$*

*and  $m2 = M \sin X 0.05 = 95.2381 \text{ N.m}$*

*that is to say  $M =$*

*$M2$*

*$2$*

*$1 + m2 = 119.0476 \text{ N.m}$*

*2.3*

***Results of modeling B***

***6.1 Values***

***tested***

*One tests moments  $M_{XX}$  and  $M_{YY}$ . These values are given in the local reference mark to the plate,*

*chosen*  
*parallel at the sides.*

*One thus has:  $M_{XX} = M_{YY} = M = 2,38095 \cdot 10^3 \text{ NR}$  as the moment is uniform in the plate, it is enough to test the values maximum and minimum of the moments and to check that they are both equal to  $M$ :*

***Handbook of Validation***

***V7.12 booklet: -***

***Document: V7.12.303***

***HSLA303 - Roll under pressure and dilation  
thermics***

***Summary:***

***Calculation is carried out into axisymmetric. The goal of the test is to validate the initial deformations  
(key word  
EPSI\_INIT).***

***The cylinder is subjected to a homogeneous thermal dilation (T constant).***

***The followed procedure is as follows:***

.

***that is to say 1 the field of deformations resulting from one the 1st calculation, the cylinder being  
subjected to a dilation***

***homogeneous thermics T (U1 the field of resulting displacements),***

.

*in the second calculation, the cylinder is subjected to an internal pressure, with like deformations initial the field of deformations 1 (either **U2** the resulting field of displacements),*

*one then compares the results with the field **U**, obtained with cylinder under pressure, but without initial deformations. One must have the relation:  $U2 = U + U1$ .*

## **4.2 Remarks**

.

*The goal of the test is not to obtain a high degree of accuracy on the level of the results, but simply to check the relation:  $U_2 = U + U_1$ ; so calculation was carried out only with one grid coarse.*

.

*It is noted that the required relation is well checked at the loose lead of the cylinder.*

.

*It is checked in addition that the field of deformation resulting from thermal dilation is uniformly equal to  $1.2 \times 10^{-3}$ .*

**POST\_K\_BETA**

**Summary:**

*This test validates the operation of the order POST\_K\_BETA which calculates the factors of intensity of constraints with the two points of defects, using the constraints with the nodes resulting from the mechanical resolution.*

*This test breaks up into two type of modeling:*

- *EPICU01a: axisymmetric modeling,*
- *EPICU01b: modeling 3D.*

*Handbook of Validation*

*V7.14 booklet: Thermomechanical linear statics of the voluminal systems*

### **1.1.1 Defect considered**

*In the method K, the defect is not modelled in the grid. The grid makes it possible to calculate constraints with the nodes. A postprocessing is then applied to calculate the factor of intensity constraints by the method starting from the constraints with the nodes (the method is detailed in [R7.02.10]).*

*For this test, the defect considered is elliptic and of longitudinal orientation. Its dimensions are them following (see figure which follows):*

- depth:  $prof\_def = 6mm$
- width:  $2b = 60mm$
- shift in the coating:  $decaf = 0,2mm$

## ***HSLV304 - Roll under thermal loading***

### ***Summary:***

***The goal of the test is to validate a decomposable thermal loading in 2 harmonics, applied to one axisymmetric structure (cylinder in fact).***

***The harmonics considered are harmonics 1 and 2.***

***The comparison is carried out compared to a model hull, with a software finite elements.***

***In modeling B, one imposes a field of initial deformations  $O$  defined by AFFE\_CHAR\_MECA, corresponding to the field of deformations resulting from model A. the goal is to compare the results compared to those obtained for model A.***

## ***Handbook of Validation***

### ***V7.15 booklet: Thermomechanical linear statics of the voluminal systems (formation)***

#### ***V7.15.100 document***

### ***FORMA01 - Work practise formation of base with the use of Code\_Aster***

#### ***Summary:***

***This test corresponds to practical work of the basic training to the use of Code\_Aster. It is about one bent piping, made up of a linear elastic material, subjected to various loadings: force applied with the end, internal pressure, thermal transient.***

***Modelings used are as follows:***

- ***modeling a: beams (POU\_D\_T), which corresponds to the TP1,***
- ***modeling b: hulls DKT, grid GIBI,***
- ***modeling F: hulls DKT, grid GMSH, identical (with the grid near) to modeling B,***
- ***modeling C: solid elements 3D, grid GIBI,***
- ***modeling D: beams (POU\_D\_T), dynamic calculation,***
- ***modeling E: elements PIPE.***
- ***Modélisation G: solid elements 3D, (linear grid GMSH),***
- ***Modélisation H: solid elements 3D, (quadratic grid GMSH).***

***The chapter 1 “Problem of reference” presents the problem to be treated and the data common to all modelings; the statements of Practical Work of the formation are included in it document:***

- ***TP1: “beams” to see modeling A,***
- ***TP2: “hulls” to see modeling F,***
- ***TP3: “thermoelastic 3D” to see modeling H,***

· **TP4: “dynamic” to see modeling D.**

**Problem of reference**

**1.1 Geometry**

**The study relates to a piping including/understanding two right pipes and an elbow [Figure 1.1-a].**

**The geometrical data of the problem are as follows:**

- **length LG of the two right pipes is 3 m,**
- **the Rc ray of the elbow is 0.6 m,**
- **the angle of the elbow is 90 degrees,**
- **the thickness of the right pipes and the elbow is 0.02 m,**
- **and the ray external Re of the right pipes and the elbow is of 0.2 Mr.**

**Appear 1.1-a**  
**Note:**

**The geometry of the problem has a symmetry compared to the plan (A, X, Y).**

**1.2**  
**Material properties**

**For all modelings:**

**Isotropic linear elastic material. the properties of material are those of A42 steel:**

· **the Young modulus  $E = 204.000. 10+6 \text{ N/m}^2$ ,**

· **the Poisson's ratio = 0.3,**

· **For thermoelastic calculation (modelings C, G H)**

-  
**the thermal dilation coefficient =  $10.92 106/^{\circ}\text{C}$ ,**

-  
**thermal conduction =  $54.6 \text{ W/m } ^{\circ}\text{C}$ ,**

-  
**voluminal heat CP =  $3.71 106 \text{ J/m}^3 ^{\circ}\text{C}$ ,**

· *For dynamic calculation (modeling D)*

-

*The Young modulus is worth 210.000. 10+6 N/m<sup>2</sup>*

-

*density = 7800 kg/m<sup>3</sup>,*

*- the damping of the clean modes will be taken to 2% for the first 2 modes, 3% for 3rd, 4% for the fourth and 5% for the fifth.*

### **1.3**

#### ***Boundary conditions and loadings***

*The boundary conditions for all modelings are as follows:*

- *for the mechanical loadings, there is an embedding on the level of section A,*
- *for the thermomechanical loading, there is embedding on the level of section A and of section B.*

*With regard to static calculations (modeling A, B, C, E, F, G, H), the loadings applied are of three types:*

- *constant force  $FY = 100.000. NR$  directed according to the axis Y and applied to the section B,*
- *pressure interns  $P = 15. E+6 N/m^2$ , (modelings B, C, E, F, G, H)*
- *thermomechanical loading with a transient of temperature imposed on the face intern of piping (gone up 20°C with 70°C in 10 seconds) and a condition of exchange no one on the external face of piping (heat insulator) (modeling C only).*

*With regard to dynamic calculation (modeling D), the loading applied is a force transient (in Newton):*

$$FY(T) = 1\ 00.000. * \cos(2 ** Freq1 * t)$$

*directed according to the axis Y and applied to the section B,*

$$Freq1 \text{ such as } 2 * Freq1 = 121 \text{ rad/s.}$$

***Page:***

***6/28***

***3 Modeling***

***With***

***3.1***

***Characteristics of modeling***

***3.1.1 Grid***

***GMSH***

***The telegraphic grid could be built inter-actively using GMSH (or GIBI). It is enough to define the points A, B, C D, then the two lines AC and dB, item 0 and rings it BC. Size of the elements could be defined like parameter. In GMSH, one will be able to declare “physical” the points A and B, then lines AC and data base, then circle BC. Once grid carried out, to save it (format msh).***

***The elbow will be modelled initially by at least four elements of right beams (to provide for GMSH a density lower than 0.25).***

***With regard to the right pipes, the discretization does not have an influence on the result, because them***

***elements of right beam of Timoshenko (POU\_D\_T) of Code\_Aster provide results correct with the nodes of the grid, even for a discretization with very little element, in LINEAR STATICS only [R3.08.01].***

***3.2***

***To drive orders Aster***

- Lecture of grid (PRE\_GMSH) and generation of grid (LIRE\_MAILLAGE).***
- Définition of the finite elements used (AFFE\_MODELE). One will affect initially to group meshes composing the elbow, as on the right parts, modeling POU\_D\_T.***
- Définition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU).***

*The mechanical characteristics are identical on all the structure.*

- *Affectation of the characteristics of the elements beams (AFFE\_CARA\_ELEM).*  
*The section of all the pipes is circular.*

- *Définition of the boundary conditions and loading (AFFE\_CHAR\_MECA).*  
*Piping is embedded in its base, on the level of point A.*

*The loading is a specific force FY applied to the point B.*

- *Résolution of the elastic problem (MECA\_STATIQUE).*  
*Calculation of the field of efforts generalized by element with the nodes, the field of calculated displacement (option “EFGE\_ELNO\_DEPL”).*

- *Impression of results (IMPR\_RESU).*  
*One will print in form listing displacement at the point B and the maximum values of efforts.*

*One will also print the field of displacement to format GMSH, for one visualization of the results with GMSH. (to use DEFUFI to define the output file).*

*Optional calculation: curved beams and coefficient of flexibility*

*One will be able to check the impact of a coefficient of flexibility of the elbow on displacements with not B. This coefficient of flexibility is defined in the level of order AFFE\_CARA\_ELEM (key word DEFI\_ARC).*

*It will then be necessary to assign to the group of meshes composing the elbow modeling POU\_C\_T.*

- *Définition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU). mechanical characteristics are identical on all the structure.*
- *Affectation of the characteristics of the elements hulls (AFFE\_CARA\_ELEM): thickness*
- *Définition of the boundary conditions and loadings (AFFE\_CHAR\_MECA).*
- *Piping is embedded in its base, on all the nodes located in the Y=0 plan. piping presents a symmetry plane Z=0.*
- *One calculates two loading cases:*
  - *an effort distributed  $F^*$  directed according to the axis Y and applied to the section B, (the effort distributed is such that the resultant  $2\pi r \cdot F^* = F_Y$ ,  $F_Y$  being the total force which one wishes to apply). To apply the effort to the section B, FORCE\_ARETE will be used,*  
*-*  
*a pressure interns P.*

**Note:**

*The value of the pressure  $P$  is positive according to the contrary direction of the normal with the element. To direct this normal MODI\_MAILLAGE should be used/  
ORIEN\_NORM\_COQUE: to define in A1 a vector giving the direction of the normal (opposed to the pressure).*

- *Résolution of the elastic problem for each loading case (2 calls to MECA\_STATIQUE).*
- *Impression of results (IMPR\_RESU).*
- *One will print in form listing displacement for each result on the section B. One will also print with format GMSH, displacements.*

*One will be able in the second Aster calculation to evaluate the constraints with the nodes:*

- *One adds in the characteristics hulls (AFFE\_CARA\_ELEM) the vector  $V$  defining it locate examination (key word ANGL\_REP). One can take for example  $V=Oz$ .*
- *Calcul of the stress field by elements to the nodes for each loading case (option "SIGM\_ELNO\_DEPL"). The constraints are calculated in the definite local reference mark for each element using the vector  $V$  (preceding key word ANG\_REP). To use NIVE\_COUCHE for to define the level of calculation in the thickness.*

## **7.2**

### **Characteristics of the grid**

**4240 meshes HEXA20, 5913 nodes**

## **7.3 Orders**

### **Aster**

**In the case of load thermal, the study requires the first transitory thermal calculation followed of one mechanical calculation.**

**In order to use the possibilities of recovery of a calculation, one will make two successive and coupled executions with Aster. In the first execution, one will make the resolution of the various loading cases, in second of postprocessings on the thermomechanical loading case.**

**The principal stages of the first execution with Aster will be:**

**Reading of grid (PRE\_GIBI) and generation of grid (LIRE\_MAILLAGE) in elements quadratic.**

- Définition of the finite elements used (AFFE\_MODELE). One will define a model for calculation thermics and a mechanical model.**
- Définition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU). thermal characteristics and mechanics are identical on all the structure.**

- **Définition of the boundary conditions thermal (DEFI\_FONCTION and AFFE\_CHAR\_THER\_F):**  
**There is a transient of temperature imposed on the interior surface of piping (assembled of 20°C with 70°C in 10s). It is considered that piping is insulated and thus one applies a condition of null exchange on external surface.**
  - **Résolution of the thermal problem (THER\_LINEAIRE). The calculation of the field of temperature be carried out for the two moments of the transient (5. and 10. S).**
  - **Définition of the three mechanical loading cases: boundary conditions and loading mechanics or thermics (AFFE\_CHAR\_MECA):**
    - **an effort FY directed according to the axis Y and applied to the section B, (to use FORCE\_FACE. value of the surface effort of Fy resultant can be calculated in Aster using DEFI\_VALEUR),**
    - **an internal pressure,**
    - **the thermal transient previously calculated,**
    - **piping is embedded in its base (Ae1, Ai1, Ae2, Ai2), on all the nodes located in the plan of Y=0 equation. In the case of load thermal, the section B of piping is also embedded.**
  - **Résolution for the various loading cases from the mechanical problem and calculation of the field of constraints with the nodes by element (3 calls to MECA\_STATIQUE)**
  - **Using CALC\_ELEM, calculation of the constraints by elements extrapolated with the nodes (SIEF\_ELNO\_ELGA) and of the equivalent constraints of Von Mises (EQUI\_ELNO\_SIGM).**
  - **Impression of results (IMPR\_RESU).**
    - **One will print in form listing on the one hand displacement on the section B, and of other leaves the maximum values the tensor of constraints, in the case of load mechanics.**
    - **One will print for thermomechanical calculation, displacements, and the component VMIS on field EQUI\_ELNO\_SIGM with format CASTEM.**

***9 Modeling***

***D***

***9.1***

## ***Characteristics of modeling***

***The geometry is identical to that of modeling A. the grid must be enough fine to obtain a correct solution in dynamics, in particular to describe the clean modes correctly: bend and the right pipes will be modelled chacuns by at least 5 elements of right beams of Timoshenko POU\_D\_T.***

***One first of all wishes to know the first clean modes.***

***Then one will make a transitory analysis of the response of the pipe to the sinusoidal force between 0.0 and 2.0 S.***

***The structure is initially at rest. One will be able initially to make the analysis on basis modal. One will be able to compare the results of the analysis on modal basis with a direct analysis on base physical.***

## ***9.2***

### ***Characteristics of the grid***

#### ***9.2.1 Grid***

##### ***GMSH***

***The grid will be obtained with GMSH, as for modeling A. Attention not being forgotten in the command file ASTER to create the groups of “physical” meshes and, then, in command file ASTER to create the groups of nodes corresponding to the groups of meshes thanks to order DEFI\_GROUP.***

#### ***9.2.2 Alternative grid: with GIBI***

***For those which prefer GIBI, one will be able to create the grid using this maillor, in the following way:***

***one will create with the editor a data file which will include/understand the list of the instructions that one will subject***

***with GIBI. The various stages of modeling with GIBI will be:***

***· Définition of the options of grid by the procedure OPTION.***

***The co-ordinates of the points will be introduced in dimension 3.***

***The elements will be of type SEG2.***

***· Définition of the points A, B, C, D, O.***

***The points will be named Pa, PB, PC, PD, PO.***

***· Maillage of piping***

***For the grid of piping, one will use the operators RIGHT-HAND SIDE, CIRCLE and AND.***

***Cutting will be of only one element for the right pipes and the elbow.***

- *Visualisation of the final grid.*

*Visualization is made by the procedure TRACE, for which one must specify a point, which indicate the position of the eye which looks at the object.*

- *Sauvegarde of the grid for its use in Aster.*

*To be able to read again the grid by Aster it should be safeguarded in a formatted file, this safeguard is made by the procedure SAVE with the key word FORMAT. The file which will be creates the same name will have as the data file GIBI, but will have as an extension “.mgib”.*

- *Arrêt of the execution of GIBI.*

*To leave GIBI it should be indicated by the directive END.*

*Note:*

*Any instruction GIBI ends in the symbol “;”.*

## **9.3 Orders**

***Aster***

The principal stages of calculation with *Aster* will be:

### **9.3.1 Preparation of the data and analyzes modal**

- **Maillage (not to forget the PRE\_GMSH or the PRE\_GIBI).**
- **Définition of the finite elements used (AFFE\_MODELE).**
- **One will use the groups of meshes envisaged in GMSH (or GIBI).**
- **Définition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU).**
- **The mechanical characteristics are identical on all the structure.**
- **Affectation of the characteristics of the elements beams (AFFE\_CARA\_ELEM).**
- **The section of all the pipes is circular, of ray 0.2 m and thickness 0.02 Mr.**
- **The elbow constitutes of an arc of circle of center the point O and ray 0.6 Mr. to define the curved element, one will use key word DEFI\_ARC.**
- **Définition of the boundary conditions and loading (AFFE\_CHAR\_MECA). Point A is embedded.**
- **Définition of the matrices of the elastic problem (MACRO\_MATR\_ASSE).**
- **Calcul of the first 5 clean modes (MODE\_ITER\_SIMULT).**

- **Impression of the clean modes (IMPR\_RESU):** one will print the grid and the modes with the format GMSH for a visualization in GMSH (or with format CASTEM, for a visualization of results with GIBI). In the case of GMSH, not to forget to open the logical unit of the file of postprocessing by a DEFUFI!

### 9.3.2 Analyze transient

#### Construction of the specific force

- **Définition of the load forces at the point B (AFFE\_CHAR\_MECA FORCE\_NODALE).**
- **Calcul of the elementary vectors forces (CALC\_VECT\_ELEM).**
- **Assemblage of the vector forces (ASSE\_VECTEUR).**
- **Définition of the function evolution of time (FORMULA).**

#### Transient on modal basis

- **Projection of the problem assembled on the basis of clean mode (MACRO\_PROJ\_BASE).**
- **Transitory Calcul by modal recombination (DYNA\_TRAN\_MODAL).**
- **Récupération of displacements, speed in there of B, C, D (RECU\_FONCTION).**
- **Impression of these functions to the format listing and AGRAF (IMPR\_COURBE).**
- **One will be able to possibly determine the constraints MIN and MAX due to the efforts generalized during the transient while passing by a restitution on the physical basis (REST\_BASE\_PHYS), a calculation of constraints (CALC\_ELEM), a skilful postprocessing for to calculate the maximum in the course of time (CREA\_CHAMP) and a writing in the file result (IMPR\_RESU).**

*Handbook of Validation V7.15 Booklet: Thermomechanical linear statics of the voluminal systems (formation)*

*HT-66/03/008/A*

---

**Code\_Aster ®**

**Version**

**6.4**

**Titrate:**

**FORMA01 - TP of the basic training to the use of Code\_Aster**

**Date:**

**16/05/03**

**Author (S):**

**J.M. PROIX, I. BAKER, E. BOYERE**

**Key: V7.15.100-B**

**Page:**

**15/28**

## **Direct calculation on physical basis: transient on physical basis**

- **Direct transitory Calcul by Newmark (DYNA\_LINE\_TRAN).**
- **Récupération of displacements, speed in there of B, C, D (RECU\_FONCTION).**
- **Impression of these functions to the format listing and AGRAF (IMPR\_COURBE).**
- **Calcul of the MAX (space and temporal) of the constraints due to the generalized efforts.**

### **9.3.3 Postprocessings**

**One will visualize with GMSH or GIBI the grid and the first five clean modes of the structure. One will also trace using AGRAF the evolution of displacements according to time at the points B, C and D.**

**Lastly, one will be able to determine the maximum (and minimum) space and temporal of the constraints due to generalized efforts, in order to consider the requests maximum which the pipe during this test undergoes.**

#### **9.3.3.1 Helps for postprocessing with GMSH**

**Postprocessing in GMSH is rather intuitive. However some points are to be known:**

- **One must put GMSH in *Post-Processing* mode.**
- **In *Tools/Options*, the Aspect mitre makes it possible to specify *Displacement* like *Vector display*, i.e to observe the modes like a structural deformation. One will be able to also specify the amplitude of the deformation thanks to the box *Vector size*.**
- **The *Step* button of the *General* mitre makes it possible, as for him, to make ravel the various modes (which is seen in GMSH like “steps of time”).**

#### **9.3.3.2 Helps for postprocessing with GIBI (possibly)**

**One will provide a command file GIBI allowing to carry out graphic postprocessings. Principal orders GIBI used are:**

**\* Second reading of the file result to format “CASTEM” coming from *Aster*:**

**OPTI REST FORMAT “nom\_de\_fichier.cast”;**

**REST FORMAT;**

**\* Recovery of the number of moments calculated in the object “resu” resulting of *Aster***

**ninst = DIME resu;**

**\* One can post it:**

**LIST ninst;**

**i=0;**

**\* Buckle over every filed moment:**

**to repeat ninst boucl1:**

**I = i+1;**

**Ti = resu. I. inst;**

**\* Recovery of the fields of displacements in the result:**

**C = resu. I. depl;**

**\* visualization of the deformation**

**defo1 = defo red email C 100.;**

**defo0 = defo email green C 0.;**

**titrate “deformed Piping urgent” Ti;**

**trac oe (defo1 and defo0);**

**end boucl1;**

***16/28***

### **9.3.3.3 Helps for postprocessing with AGRAF**

**Visualization of curves of results printed with format AGRAF. In the continuation, one will replace**

**<résultat> by the name of the file result of the type AGRAF produced by order IMPR\_COURBE in the command file.**

**The various stages of the visualization of the results with AGRAF are:**

- launching of AGRAF: to type “agraf” in a window Unix,**
- opening of a file Directives: small Directives (cf Table 1),**
- to select To open, give a name of directive by the BSF (for example <résultat>.digr),**

to click in the BSF on Opening Directive, and confirming the creation of a new file of directives,

- reading of the results resulting from Aster: small Data (cf Table 1),
- to select the file <résultat>.dogr thanks to the BSF,
- definition of the graph to be traced: small Graphs,
- to select To specify/a window entitled Spécification of the curves of a graph opens,
- a Titre zone makes it possible to give a title to the graph, to replace Nouveau graph by titrate your graph (ex: Displacement of the pipe) - in lower parts, actionable with wish by a toggle-short prop, appear of the lines of definition of the curves to trace,
- zone Abscisses one defines the n° table and the n° of the column constituting the data in to put in X-coordinates of the curve (1 1 for the L era curves),
- zone Ordonnées one defines No of the table and No of the column constituting the data in to put in ordinates of the curve (1 2 for the first curve),
- zone Marqueur one defines the shape of the marker, the periodicity of layout of this marker (all N points of the curve), (10),
- Légende zone makes it possible to give a text of legend following the curve curve (DY-B),
- to click on Safeguarding to record the definition of the graph,
- Sauvegarde and actualization of the graph to be traced: small Graphs,

-  
button To safeguard,

-  
button To trace,

- Impression POSTSCRIPT of the graph: fenestrate Tracé,
- button To print the Layout,

normal SN

In addition to this result of nonregression, one can observe displacement according to Y of the point D:

One observes that the modes of the structure are excited during the first second transient, it who explains the chahutée shape of the curve of displacement. Then movements of the modes clean are deadened and there remains only the stationary movement regulated on the frequency of sinusoidal force at the point B.

***Page:***

***20/28***

### **13.2 Characteristics of the grid**

**700 meshes QUAD4, 2240 meshes TRIA3, 1344 nodes**

**Grid GMSH built in quadrilaterals and triangles is available in the base of the tests: geometrical data file names forma01f.datg. (to change the extension into “.geo”). It the numbers of the entities “physical corresponds to the geometry above (to find” which correspond to the groups of meshes, to use Tools/Visibility/Physical). The groups correspond with:**

**GM30 <=> surface of the PIPE**

**GM28 <=> section B (effort)**

**GM31 <=> not A1 (- R, 0, 0)**  
**GM27 <=> section A (embedding)**  
**GM29 <=> SYMMETRY**

### **13.3 Orders**

#### **Aster**

• **Lecture of grid (PRE\_GMSH) and generation of grid (LIRE\_MAILLAGE). One can to use DEFI\_GROUP to re-elect the groups of meshes according to the correspondence:**

**# GM30 <=> PIPE**  
**# GM28 <=> EFOND**  
**# GM31 <=> A1**  
**# GM27 <=> ENCAST**  
**# GM29 <=> SYMMETRY**

- **Définition of the finite elements used (AFFE\_MODELE). The right pipes and the elbow will be modelled by elements of hull (DKT).**
- **Réorientations of the normals to the elements: one will use MODI\_MAILLAGE to direct all elements in the same way, with a normal turned towards the interior of the pipe (being data the convention of sign on the pressure) in order to give a positive value to pressure.**
- **Définition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU). mechanical characteristics are identical on all the structure.**
- **Affectation of the characteristics of the elements hulls (AFFE\_CARA\_ELEM): thickness**
- **Définition of the boundary conditions and loadings (AFFE\_CHAR\_MECA).**
- **Piping is embedded in its base, on all the nodes located in the Y=0 plan. piping presents a symmetry plane Z=0.**
- **One calculates two loading cases:**
  - **An effort distributed  $F^*$  directed according to the axis Y and applied to the section B, (the effort distributed is such as the resultant  $2\pi i \cdot R_{moy} F^* = F_Y$ ,  $F_Y$  being the total force which one wishes to apply). For to apply the effort to the section B, one will use FORCE\_ARETE.**
  - **A pressure interns P. Remarque: The value of the pressure p is positive according to the direction opposite of the normal to the element. To direct this normal it is necessary to use**

**MODI\_MAILLAGE/ORIEN\_NORM\_COQUE:** to define in A1 a vector giving the direction of normal (opposed to the pressure).

- Résolution of the elastic problem for each loading case (2 calls to MECA\_STATIQUE).
- Impression of results (IMPR\_RESU).
- One will print in form listing displacement for each result on the section B. One will also print with format GMSH, displacements.

**One will be able in the second Aster calculation to evaluate the constraints with the nodes:**

- One adds in the characteristics hulls (AFFE\_CARA\_ELEM) the vector V defining it locate examination (key word ANGL\_REP). One can take for example V=Oz.
- Calcul of the stress field by elements to the nodes for each loading case (option "SIGM\_ELNO\_DEPL"). The constraints are calculated in the definite local reference mark for each element using the vector V (preceding key word ANG\_REP). To use NIVE\_COUCHE for to define the level of calculation in the thickness.

*Aster*

**In the case of load thermal, the study requires the first transitory thermal calculation followed of one mechanical calculation.**

**In order to use the possibilities of recovery of a calculation, one will make two successive and coupled executions with *Aster*. In the first execution, one will make the resolution of the various loading cases, in second of postprocessings on the thermomechanical loading case.**

**The principal stages of the first execution with *Aster* will be:**

- **Lecture of grid (PRE\_GMSH) and generation of grid (LIRE\_MAILLAGE) in elements linear. One can use DEFI\_GROUP to re-elect the groups of meshes according to correspondence:**

**PIPE <=> GM10000**

**EFOND <=> GM10005**

**ENCAST <=> GM10001**

**SYMMETRY <=> GM10002**

**SURFINT <=> GM10004**

**SURFEXT <=> GM10003**

- **Définition of the finite elements used (AFFE\_MODELE). One will define a model for calculation thermics and a mechanical model.**

- **Définition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU). thermal characteristics and mechanics are identical on all the structure.**

- **Définition of the boundary conditions thermal (DEFI\_FONCTION and AFFE\_CHAR\_THER\_F):**

**There is a transient of temperature imposed on the interior surface of piping (assembled of 20°C with 70°C in 10s). It is considered that piping is insulated and thus one applies a condition of null exchange on external surface.**

- **Résolution of the thermal problem (THER\_LINEAIRE). The calculation of the field of temperature be carried out for the two moments of the transient (5. and 10. S).**

• **Définition of the three mechanical loading cases: boundary conditions and loading mechanics or thermics (AFFE\_CHAR\_MECA):**

- **an effort FY directed according to the axis Y and applied to the section B, (to use FORCE\_FACE.**

**value of the surface effort of Fy resultant can be calculated in Aster using DEFI\_VALEUR),**

- **an internal pressure,**

- **the thermal transient previously calculated,**

- **piping is embedded in its base (Ae1, Ai1, Ae2, Ai2), on all the nodes located in the plan of  $Y=0$  equation. In the case of load thermal, the section B of piping is also embedded.**

## **19 Summary of the results**

The purpose of this test is not to validate functionalities, but is used for the formation. However, it is interesting to compare certain modelings of the same problem. It is noted that the variations remain relatively weak (5% of variation to the maximum between 3D (quadratic elements), hull and pipe).

### ***V7.15 booklet: Thermomechanical linear statics of the voluminal systems (formations)***

#### ***V7.15.101 document***

## ***FORMA08 - Work practise Postprocessing 3D***

### ***Summary:***

***This test corresponds to the TP 3D of the formation to the post treatment using Code\_Aster (postprocessing of one calculation of piping bent in 3D).***

***This TP is the continuation of the TP of the basic training Aster included in the case test forma01c describes in documentation of validation [V7.15.100].***

***It is about a bent piping made up of a linear elastic material. One considers only one case of loading (force applied at the end of the elbow).***

***In this T.P, one is interested in the operators of post following treatment:***

- Opérateurs allowing to define groups of entities of the type grid (DEFI\_GROUP for definition and the handling of groups of nodes and meshes, MODI\_MALLAGE for reorientation of the elements of face subjected to a pressure).***
- Total Opérateurs allowing to enrich the concepts results (CALC\_ELEM for calculation of fields with the elements, CALC\_NO for the calculation of the fields to the nodes).***
- Impressions (IMPR\_RESU for the impression of the results to the formats RESULT, IDEAS, GIBI)***
- Localised Dépouillements (POST\_RELEVE\_T for the statement of values on lines or groups nodes and calculation of derived quantities).***
- Tracé of curve (IMPR\_COURBE for the visualization of the evolution of a size according to time or of space).***

***HSNA100 - Drying of a concrete enclosing wall***

## **Summary:**

*This case test is intended to not validate the calculation of the drying of the concrete, developed in the operator of thermics linear of Code\_Aster. The studied case corresponds to the simulated drying of the enclosure of Flamanville. Data geometrical and the characteristics materials result from the thesis of Laurent Granger "Behavior differed from the concrete in the enclosures of nuclear thermal power stations " published by the Central Laboratory of the Bridges and Roadways (1996, pages 185 to 204).*

*Drying is carried out by exchange with outside, on the walls internal and external of the wall, in modeling axisymmetric 2D. It is carried out over one 54 years duration.*

*The coefficient of diffusion of drying depend on the temperature, the analysis is made up of the chaining of one thermal calculation and of a calculation of drying. One carries out then a mechanical calculation of withdrawal in elasticity linear and in plasticity Von Misès with an isotropic work hardening.*

***1.3***  
***Boundary conditions and loadings***

***For thermal calculation:***

*The temperatures are imposed on the walls interior and external of the enclosing wall (groups meshes  $l\_int$  and  $l\_ext$ ).*

*During the first five years, the imposed temperature is of 15°C on each wall:*

$$\begin{aligned} T \\ T \\ = \text{°} \\ 15 \text{ C} \\ int = ext. \end{aligned}$$

*From the fifth year, the temperature in internal wall passes to 35°C:*

$$\begin{aligned} T \\ = \text{°} \\ 35 \text{ C and } T \\ = \text{°} \\ 15 \text{ C} \\ int \\ ext. \end{aligned}$$

*In practice, the scales of time of drying being much higher than that of thermics, one can to consider that thermal balance is quasi immediate. Calculation is carried out in linear thermics.*

***For the calculation of drying:***

*The boundary conditions are expressed in term of normal flow of moisture on the walls internal and external of the enclosure (groups of meshes  $l\_int$  and  $l\_ext$ ). One uses option FLUX\_NL of the operator AFFE\_CHAR\_THER\_F. Normal flow is expressed generally, in a calculation of drying, in function of the initial concentration  $C_0$  and the external concentration  $C_{eq}$ , in the form:*

$$\begin{aligned} C \\ , \\ 0 \\ 5 \\ W = - D (C, T) \\ = \\ C - 2 C - C \\ C - C \end{aligned}$$

$$\begin{aligned} N \\ (C \\ 2 \\ 0 - C \\ ) [ \end{aligned}$$

$(eq)](eq)$

$eq$

$with = 3.41557.108$

*The data retained in the case of the enclosure of Flamanville are as follows:*

$C = 105\ 7$

$,\ L/m^3$

$0$

*(initial concentration)*

*On the interior face:*

*from 0 to 5 years,*

$C$

$L\ m$

$eq = 69\ 1$

$3$

$,$

$/$

*from 5 to 54 years,*

$C$

$L\ m$

$eq = 51\ 6$

$3$

$,$

$/$

*On the outside:*

$C$

$L\ m$

$eq = 69\ 1$

$3$

$,$

$/$

*The expression of flow is interpolated by Code\_Aster, according to the current price of water concentration, (variable of calculation). One uses an interpreted function, to define sound expression, according to the formulation above (operator FORMULATES), and operator CALC\_FONC\_INTERP to define the corresponding tabulée function.*

*The calculation of drying is carried out in nonlinear thermics, by chaining with thermal calculation linear.*

## **1.4 Conditions initial**

*The initial conditions are consisted the initial temperature, which one takes with 15°C, and initial water concentration, which is worth  $C = 105 \text{ 7}$   
, L/m<sup>3</sup>  
0  
.*

## **Reference solution**

2.1

### **Method of calculation used for the reference solution**

*The reference solution is consisted the calculation carried out with a similar modeling by L. Granger, within the framework of its thesis [bib1]. The case test relates to the calculation carried out with the data  
experimental corresponding to the enclosure of Flamanville. The implementation and the results are there  
described pages 185 to 204.*

*Drying is carried out over 54 years, by taking account of the change of boundary conditions at the time of the fifth year.*

## **2.2**

### ***Results of reference***

*Water concentration in the middle of the enclosure, at the end of 5, 15, and 54 years.*

## **2.3**

### ***Uncertainty on the solution***

*One does not have that water concentrations calculated within the framework the thesis of Laurent Granger, without numerical data on uncertainty of the solution, with regard to the enclosure of Flamanville.*

## **7 Modeling**

**C**

### **7.1**

#### ***Characteristics of modeling***

*It is a question here of comparing the mechanical fields resulting from orders MECA\_STATIQUE and STAT\_NON\_LINE. Those must be identical provided that the initial water concentration is null. Indeed, the withdrawal of dessication is equal to  $(T) = (C(T) - C_0)$*

*0 for incremental calculation*

*(STAT\_NON\_LINE) and  $(T) = C(T)$  in MECA\_STATIQUE since calculation does not take account of history of material. One then affects a water preconcentration equal to  $C_0$  by the operator CREA\_CHAMP and one replace the running water concentration  $C(T)$  by  $C(T) - C_0$  using operator COMB\_CHAM\_NO.*

*One uses same axisymmetric modeling as A, with the same space discretization and temporal. Only the mechanical loading is modified, one removes the mechanical pressures exerted on the enclosure as well as thermal dilation (by cancelling the dilation coefficient) so to isolate the withdrawal from with drying.*

### **7.2**

#### ***Functionalities tested***

*The functionalities tested are those of other modelings plus the following ones:*

#### ***Orders Options***

*CREA\_CHAMP “AFFE”  
“NOEU\_TEMP\_R”*

*CREA\_CHAMP “EXTR”  
“NOEU\_TEMP\_R”*

*COMB\_CHAM\_NO*

## **8** *Results of modeling C*

### **8.1 Values tested**

*Displacement at the A2 point:*

*Identification Reference Stat\_Non\_Line Aster  
Aster Méca\_Statique %  
difference*

*DX (N47)*

*8.7688E-4*

*8.9645E-4 8.7688E-4*

*2.2*

*The value of reference selected is that obtained by operator MECA\_STATIQUE.*

## **9** *Summary of the results*

*For modeling A, the precision of the results reaches approximately 1.5% for the water concentration compared to the reference solution which one does not know the proper precision.*

*The test was also carried out on a grid much coarser (4 elements in the direction radial), and the results are also good in the center of the concrete structure.*

*For modeling B, the difference reaches 2.5% on the concentrations because of a grid 3D relatively coarse.*

*This test makes it possible of more than check nonthe regression of the code for the calculation of drying in*

*the nonlinear operator of mechanics. The law of behavior chosen, as well as the field of moisture resultant do not make it possible to know simple analytical solution. Convergence in thermics nonlinear is delicate with the first step of time, to find the first state of balance, because of the important scale of the steps of time. Modeling C makes it possible to take account of a concentration out of nonnull initial water in a calculation carried out with operator MECA\_STATIQUE.*

### **FORMA09 - TP of the formation thermoplasticity**

#### **Summary:**

***This test in quasi-static axisymmetric 2D makes it possible to illustrate on a simple case the questions relative to thermoelastoplastic modelings:***

*.*  
*for thermal calculation, it highlights the effects of going beyond of maximum, of instability of diagram clarifies and shows the contribution of the diagonalisation of the thermal matrix of mass,*  
*.*

*For mechanical calculation, it highlights the constraints due to the incompatibility of the deformations thermics, even if the cylinder is free, then incrémentaux aspects of calculation with STAT\_NON\_LINE. One shows also the influence of the temperature of reference and the temperature of definition of the thermal dilation coefficient.*

### **5.1.1 Calculation**

#### **thermics**

*To improve the results of modeling A, therefore to mitigate these goings beyond of the temperature maximum (cf [R3.06.07]), several solutions are possible:*

- one can increase the step of time, which is not always compatible with the maid apprehension of the speed of the transient (as in this case),*
- or to refine the grid, which is a good solution, but expensive in time calculation,*
- one can finally use the diagonalisation of the thermal matrices of mass, i.e. here modeling AXIS\_DIAG. One then obtains the curves marked of circles on the figures [Figure 5.1-a] and [Figure 5.1-b] Ci above. The temperature remains always lower than 100°C. It is the simplest solution.*

*If one seeks to use an explicit diagram (THETA = 0), one sees appearing a clear instability for great steps of time (curve with marker cross on the figure [Figure 5.1-a] above).*

*In conclusion, for thermal calculation, it is necessary to use THETA equal to or higher than 0.5, to have one stable diagram some is the step of time. Moreover it is necessary to use a step of sufficiently small time to apprehend the transient, but not too small to avoid the oscillations. If they appear, either the grid should be refined, or to use modeling AXIS\_DIAG, (or PLAN\_DIAG, or 3D\_DIAG).*

### **5.1.2 Thermoelastic calculation in free dilation**

*One carries out calculation with MECA\_STATIQUE, using for only loading thermal dilation. With the boundary conditions of the case not attached: null displacement following OY along side AB.*

*For mechanical calculation, it will be enough to calculate at the moment  $T = 0s$ , and  $T = 11s$  for example.*

*The constraints at the moment  $t=0s$  are null, because the field of temperature is uniform ( $T = 200^{\circ}C$ ) and remain compatible. On the other hand the deformations obtained are not null since the temperature of reference is equal to  $200^{\circ}C$ .*

*With  $T = 11s$ , or any other positive mechanical moment, one sees appearing constraints known as of compatibility thermics. Indeed, the field of temperature is not uniform any more but varies according to  $R$ .*

*This produced of the incompatible deformations, which thus generate constraints, even for one roll not attached. This situation occurs even for a linear field of temperature by report/ratio with the ray. On the other hand (cf exposed) a linear field of temperature compared to the coordinates total does not produce constraint for a not attached structure.*

### **5.1.3 Thermoelastic calculation with fastening**

*Calculation with MECA\_STATIQUE of the attached case shows the contribution of fastening on constraints (SIYY in private individual): at the moment  $T = 0s$ , the temperature of reference being equal to  $0^{\circ}C$ , the uniform field of temperature causes a uniform state of stress SIYY of  $200MPa$ , and with  $T = 11s$ , the state of constraints is different from the case not attached.*

*This modeling is correct, but is limited to the linear behaviors.*

### 5.1.4 Thermoplastic calculation with fastening

*One seeks to carry out same calculation as previously, but this time with STAT\_NON\_LINE, with COMP\_INCR=\_F (RELATION=' ELAS'), not to complicate the problem (another behavior would lead to the same observations). The list of moments provided to STAT\_NON\_LINE is:  $t=0s$ , and  $t=11s$ .*

*Since an incremental calculation is made, moment 0 is regarded as initial moment. It is not thus not calculated, and at the next moment ( $t=11s$ ), one calculates the solution due to the increase in load (thermics here) between 0s and 11s. It is noted whereas the solution obtained (displacements, constraints) is different from calculation with MECA\_STATIQUE. It is logical and coherent with the definition of calculation incremental, but it is a trap for the use. To retain: implicitly, STAT\_NON\_LINE in incremental supposes that at the initial moment, the structure is not forced, not deformed. This implies that the field of temperature must be uniform and equal to the temperature of reference.*

*It is not the case here: with  $t=0s$ ,  $TREF=0^{\circ}C$ , and  $T=200^{\circ}C$ . By not calculating this thermal dilation, it is supposed here that with  $t=0s$ , there is no deformation, and no constraint.*

### 5.1.5 Thermoplastic calculation with fastening and addition of initial conditions

*One modifies the list of moments: one adds one preliminary moment  $t=1s$  for example. In this moment, one a field of uniform temperature, equal to the temperature of reference defines. One uses for this purpose them orders CREA\_CHAMP, then CREA\_RESU to enrich the structure of data thermics results with this uniform field. One carries out then mechanical calculation, by providing the list of moments:*

*$t=1s$ ,  $t=0s$ , and  $t=11s$*

*It is noted whereas the moment  $t=0s$  is well calculated, and that the constraints are identical to the case calculated with MECA\_STATIQUE.*

***Reference solution***

***2.1***

***Method of calculation used for the reference solution***

***The 2 reference solutions are obtained by resolution of the equation of drying by differences finished using Scilab. The command file is given in appendix to possibly be able to test new models.***

***The space discretization is the same one as for Aster with knowing of the meshes of 1 Misters the discretization***

***temporal is 3600 seconds for the equation of Mensi, and 60 seconds for the equation of Bazant.***

***2.2***

***Results of reference***

***One is interested in the water concentration in the test-tube after 1h, 3j, 28j, 1.25 year, 3 years and 5 years.***

***The evolution of the profiles obtained with Scilab for the law of Mensi and the law of Bazant is visible on***

***[Figure 2.2-a] and [Figure 2.2-b].***

***Note:***

***The comparison between the solutions Scilab and Aster is visible in [§Annexe 2]: they are shown concentrations obtained in the test-tube after 1h and 5 years. The maid thus is checked correlation excluded for the solution obtained with Aster for the law of Mensi at the end of one hour when one observes an oscillation which makes much think of a violation of the principle of maximum observed in thermics (cf [bib2]). It would be thus interesting to be able to use them lumpés elements when one solves the equation of drying even if the phenomenon is accentuated here because of the boundary conditions, since one directly imposes the water concentration on place to impose a flow [bib3].***

## *11 Summary of the results*

*For the whole of modelings, one obtains a difference between solution SCILAB and the solution Code\_Aster lower than 1.5% what makes it possible to validate the establishment of the various laws of drying*

*in the code. Let us note simply that one observes a violation of the principle of the maximum at the beginning of*

*simulation with Aster for the law of Mensi. This can be explained (by analogy with thermics) by the “hydrous shock” important due the made-to-order to impose the boundary conditions (water concentration*

*imposed). This problem should be able to be solved by the use of the lumpés elements of same way that in thermics.*

**Problem of reference**

**1.1 Geometry**

*A cable of section 1.71 103 and range 100 m hangs in the field of gravity, with*

temperature of 0°C. It is the seat, during 25 seconds, of a current of short-circuit which carries its temperature with 1636°C. One follows the evolution of the position of balance.

$T = 0^\circ$

$T = 1636^\circ$

## **1.2**

### **Properties of materials**

Properties of conducting metal:

$E = 5.4 \cdot 10^{10} \text{ Pa}$

$= 2761.4 \text{ Kg/m}^3$

$= 23 \cdot 10^6 \text{ }^\circ\text{C}^{-1}$

resistivity (T: temperature):  $(T) = 3.25 \cdot 10^{-8} (1 + 3.6 \cdot 10^{-3} (T - 20)) \text{ m}$

$CP = 2.457.646 \text{ J m}^3 \text{ }^\circ\text{C}^{-1}$

Convection coefficient for the losses of heat by the side wall of the cable:

$0.5 \text{ J m}^2 \text{ }^\circ\text{C}^{-1}$

## **1.3**

### **Boundary conditions and loadings**

The cable has its fixed ends. It is subjected to gravity and dilates by the Joule effect due to one current of 70.000 A during 25 seconds.

## **1.4 Conditions**

### **initial**

The cable forms a chain, at the temperature of 0°C.

## **Reference solution**

### **2.1**

#### **Method of calculation used for the reference solution**

· In first part, the test consists in checking if Aster tabule well two function-temperature of heating and cooling. They are analytical functions, of exponential nature

compared to time, resulting from the exact integration of the equation of heat independent of space but comprising a term of exchange of the Fourier type. This equation and its solution are in [bib1] [R3.08.02].

The numerical value of the coefficients is in [bib2] [U4.21.09].

· In second part, one compares the arrow of the problem of reference, at a given moment, with theoretical arrow of the chain balance static of an inextensible cable, same length, range and temperature. One can make it because the extensionnelle rigidity of the cable (produced EA) is large and that the variation in temperature is slow.

As there is not analytical solution with the problem of reference, it is admitted that one regular heating of 1600° in 25 seconds causes a quasi-static evolution. Speed of descent of the medium of the cable is indeed about 0,3 m/s, whereas the speed of one pendular motion with 0° reaches a value at least 30 times higher.

The static curve of balance of an inextensible cable whose ends are of level [2.1-a], of range  $S$ , linear weight  $W$  (gA) and of horizontal tension  $H$  has as an equation [bib3]:

$$\frac{H}{WS} Z = \cosh \left( \frac{X}{S} \right) - \cosh \left( \frac{2H}{WS} \right)$$

·  
 éq 2.1-1

From where the length  $L$  is deduced:

$$\frac{H}{WS} L = \sinh \left( \frac{X}{S} \right) - \sinh \left( \frac{2H}{WS} \right)$$

·  
 éq 2.1-2

*F*

*O (0, 0)*

*P (S, 0)*

***Appear 2.1-a: Curve of balance of a cable***

*H, which is constant along the cable since there is no horizontal force external, is given, according to [éq 2.1-2], by the transcendent equation:*

*L*

*sinh X =*

*X*

***éq 2.1-3***

*S*

*where:*

*ws*

*X =*

*.*

*2H*

*Handbook of Validation*

*V7.21 booklet: Thermomechanical nonlinear statics of the linear structures*

***Code\_Aster*** ®

*Version*

*3*

*Titrate:*

*HSNL100 - Heating of a cable per Joule effect*

*Date:*

*03/12/96*

*Author (S):*

***Mr. AUFAURE***

*Key:*

*V7.21.100-A Page:*

*4/6*

*The equation [éq 2.1-3] has a positive root  $X_0$  provided that:*

*$L > 1$ .*

*S*

*L*

*S*

*l*

*sinh X*

*X*

*$X_0$*

*The arrow  $F$  results then from [éq 2.1-1]:*

*S*

$F =$

$(\cosh X_0 - 1).$

$2 X_0$

The length of the cable with  $T O$ , which intervenes in coefficient in [eq 2.1-3], rises the length data with  $0^\circ$  by the equation of dilation:

$L(T) = L(0)$

$(1 + \alpha T).$

**HSNV100 - Thermoplasticity in simple traction**

**Summary:**

*This test treats the thermoplasticity of Von Mises with isotropic work hardening on a three-dimensional problem*

*(modeling A into axisymmetric) and two-dimensional (modeling B in plane constraints). Interest of the test*

*holds with the dependence of the elastic limit with the temperature. It also makes it possible to test the orthotropism in*

*thermoelasticity because it applies to an isotropic material then with an isotropic material declared orthotropic.*

*This makes it possible to test the functionalities of the orthotropism. One tests there also the calculation of the deformation energy.*

*Two modelings (C with element PIPE, D with element TUYAU\_6M) are added to test thermoplasticity in these elements.*

*A modeling (E) makes it possible to test the good taking into account of the variation of the coefficients of behavior VMIS\_CINE\_LINE with the temperature.*

*A modeling (F) makes it possible to test the calculation of the thermoelastic deformation energy in the beams.*

*Modeling (G) makes it possible to test the same functionalities as modelings A and B, but in 3D.*

*The solution is analytical.*

$$T$$

$$y$$

### Validity of this elastoplastic solution

It should be made sure that ()  
*L T* remains negative. Knowing that  $S T < 1$ , and that  $T > T_y$ , the preceding result confirm that ()  
 $L T < 0$ .

Lastly, it is noticed that:

$$1-$$

$$2$$

$$\operatorname{sgn}(L)$$

$$p +$$

$$= (I +)$$

$$\& \& rr$$

$$\& T$$

$$2$$

from where:

$$1-$$

$$($$

$$2$$

$$T) = (T)$$

$$rr$$

$$= (I +) T +$$

$$($$

$p(T), T [$   
 $ty, T_{fine}]$   
2

(since ( $\phantom{}$ )  
 $L(T < 0)$ ).

## **17 Summary of the results**

*The results are satisfactory and validate the behaviors thermoplastic of Von Mises with isotropic work hardening and linear kinematics. The finite elements used are the elements 2D (quadrilaterals in plane constraints or axisymetry) and the elements PIPE.*

*One notes in particular a good modeling of the variation of the elastic limit and constant of Prager with the temperature.*

**HSNV101 - Thermoplasticity and metallurgy**

**uncoupled in simple traction**

**Summary:**

***One treats the determination of the mechanical evolution of a cylindrical bar subjected to thermal evolutions***

**T T**

*() and metallurgical Z T () known and uniform (the metallurgical transformation is of bainitic type). The elements used are axisymmetric elements and the relation of behavior is the plasticity of von Mises with linear isotropic work hardening (for modeling B, one also takes account of plasticity of transformation).*

*The yield stress and the slope of the traction diagram depend on the temperature and the composition metallurgical.*

*The dilation coefficient depends on the metallurgical composition.*

*The metallurgical transformations take place with!  $p = 0$  (it is in the sense that the test uncouples plasticity from*

*transformation of traditional plasticity).*

*The results provided by Code\_Aster are very satisfactory with errors lower than 2%.*

## Summary of the results

The results found with *Code\_Aster* are very satisfactory, with percentages of error lower than 0.025% except for the deformation at moment 114 S where the error reaches 2% for modeling B.

**Handbook of Validation**

**V7.22 booklet: Thermomechanical nonlinear statics of the voluminal structures**

**Document: V7.22.103**

**HSNV103 - Thermoplasticity and metallurgy  
in plane deformations**

**Summary:**

One treats the determination of the mechanical evolution of a right-angled parallélipède in subjected plane deformations

with evolutions thermics  $T$   $T$

() and metallurgical  $Z T$  () known and uniform (the metallurgical transformation is of bainitic type).

The elements used are two-dimensional elements in plane deformations and the relation of behavior is the plasticity of von Mises with linear isotropic work hardening (for modeling B, one also holds count plasticity of transformation).

The yield stress and the slope of the traction diagram depend on the temperature and the composition metallurgical.

The dilation coefficient depends on the metallurgical composition.

For modeling A (without plasticity of transformation), the reference solution is obtained by the resolution analytical of the problem. For modeling B (with plasticity of transformation), the reference solution is obtained by the numerical resolution of the problem by using axisymmetric elements for which one impose the condition of plane deformations.

The results provided by *Code\_Aster* are very satisfactory with errors lower than 0,5%.

2

#### Reference solution (for modeling A)

### 2.1

#### Method of calculation used for the reference solution

**Before transformation**, thermoelastic solution until  $T1$  such as:

-  $O$

$HT$

$O$

y

$$\begin{aligned} \sigma_z &= - \\ E \\ &= y \, T - T = \\ &= 76, ^\circ \\ 92 \, C \end{aligned}$$

$$\begin{aligned} E + S \\ Tl = 15 \, 38 \\ , S \\ \text{thus for } T \, Tl \end{aligned}$$

$$\begin{aligned} O \\ \sigma_z &= - \\ E \, (T - T) \end{aligned}$$

**Before transformation**, and for  $T \, Tl$ , thermoelastoplastic solution such as:

$$\begin{aligned} p \\ \sigma_z &= 0 \\ \text{and } \sigma_z &= \\ R \, \sigma_z + y \\ &= (T) - \\ O \\ E \, T - T \\ p \\ y \\ ( \\ ) \\ \text{of} \end{aligned}$$

$$\begin{aligned} p \\ O \\ \sigma_z &= \\ \text{where and } \sigma_z &= - \, E \\ + \\ T - T \\ E + R \, T \\ (\sigma_z \\ ) \\ ( \\ ) \end{aligned}$$

**During the transformation**, one remains in load as long as!  $HT < 0$

$$\begin{aligned} O \\ - \\ T - \end{aligned}$$

+

 $T1 -$  $T$  $HT$  $() \text{ réf}$  $fbm$ 

2

 $! = 0 \quad T =$ 

(

 $= 538^\circ$  $82 \text{ } ^\circ\text{C}$  $2 - )$ 

,

 $T = t2 = 72,23\text{s}$ for  $T > 538,82^\circ\text{C}$ 

there is thus a thermoelastoplastic solution with phase shift:

-

 $O$  $y(T, Z) - E(Z) T - T$  $+ Z \text{ réf}$  $p$  $[(\text{ }) fbm]$  $p$  $O$  $zz =$ 

and

 $= - E$ 

+

 $Z T - T + Z$  $E + R(T, Z)$  $zz$  $(zz (\text{ }) (\text{ }) \text{ réf} fbm)$ and for  $T < 538,82^\circ\text{C}$ 

there is thus a thermoelastic solution with phase shift:

 $O$  $p$  $zz = - E(Z)$  $[(T-T) + Z \text{ réf} + zz(T$  $fbm$  $2 )]$ **After the transformation**, one replastifie when:

$$p$$

$$zz = R \left( T, Z \right) zz + y \left( T, Z \right)$$

with

$$zz$$

$$O$$

$$zz =$$

$$+ \left( T - T \right) + réf = 0$$

$$E$$

*fbm*

that is to say  $T = 267$

°

06

,

$C$

and one thus has for  $T < 267,06^{\circ}\text{C}$

$$O$$

$$E - réf$$

$$-$$

$$T - T$$

$$- y \, T, Z$$

$$p$$

$$[$$

$$fbm$$

$$($$

$$)] \, ( )$$

$$p$$

$$zz =$$

and

$$= R \, T, Z$$

$$+$$

$$T, Z$$

$$R \left( T, Z \right)$$

$$zz$$

$$( ) \, zz \, y \, ( )$$

$$+ E$$

## 4.2 Remarks

In this modeling:

$P_t$

$zz(T, Z)$

$= 0$

The error on the plastic deformation cumulated at 72 seconds comes in fact from the error made on numerical description of the metallurgical transformation which is, at this moment, from approximately 0,5%.

## 6.2 Remarks

In this modeling, one takes into account the term due to the plasticity of transformation:

$\dot{P}_t(T, Z)$

when!

Z

The reference solution is obtained by the numerical resolution of the problem with elements axisymmetric for which one imposes the condition of plane deformations.

**Document: V7.22.104**

**HSNV104 - Thermoplasticity and metallurgy in  
plane deformations with restoration  
of work hardening**

**Summary:**

One treats the determination of the mechanical evolution of a right-angled parallélipipède in plane deformations

subjected to evolutions thermics  $T$

( $T$ ) and metallurgical  $Z$  ( $T$ ) known and

uniforms (the metallurgical transformation is of bainitic type).

The elements used are two-dimensional elements in plane deformations and the relation of behavior is the plasticity of von Mises with linear isotropic work hardening. Account of the restoration is taken of work hardening, but not of the plasticity of transformation.

The dilation coefficient depends on the metallurgical composition.

The reference solution is obtained by the analytical resolution of the problem.

The results provided by *Code\_Aster* are very satisfactory with errors lower than 0,8%.

***HSNV105 - Plate in traction-shearing:  
élasto-viscoplasticity with metallurgy***

***Summary:***

***This test of nonlinear quasi-static mechanics consists in charging in traction-shearing a square plate. It is largely inspired by tests SSNP14 [V6.03.104] and SSNP15 [V6.03.105] from guide VPCS. The relation***

***of behavior which one validates here is a élasto-viscoplastic relation of behavior which one introduced***

***in Code\_Aster for the mechanical analyses taking of account metallurgy. It is an isotropic law of Norton-Hoff type with an additive work hardening which can be restored.***

***The temperature and the metallurgical state are constant, one thus considers neither plasticity of transformation nor***

***metallurgical restoration of work hardening. One does not consider either viscous restoration of work hardening.***

***The plate is modelled by a voluminal element (HEXA8).***

***The results obtained by Code\_Aster are very close to the analytical solution of reference (variation < 0.04%).***

## **2**

### ***Reference solution***

## **2.1**

### ***Method of calculation used for the reference solution***

*Being given the nature of the requests, the solution (forced, deformations and deformation figure cumulated  $p$ ) is homogeneous. In a point of the way of loading  $OA$ , one obtains:*

$$\begin{aligned} &= \\ &xx \\ &D \end{aligned}$$

$$\begin{aligned} &= \\ &xy \\ &D \end{aligned}$$

$$\begin{aligned} &= \\ &2 + 3 \ 2 \\ &eq \\ &D \\ &D \end{aligned}$$

*The elastic strain is worth:*

$$\begin{aligned} &1 \\ &exx = \\ &D \\ &E \\ &1 + \\ &exy = \\ &D \\ &E \\ &E \\ &E \\ &yy \\ &= xx \end{aligned}$$

*The viscoplastic deformation is worth:*

$$\begin{aligned} &if \\ &- R - \\ &eq \\ &C > 0: \\ &D \\ &vp \\ &xx \\ &\& = p \& eq \\ &3 \\ &D \\ &vp \\ &xy \end{aligned}$$

$$\begin{aligned} & \& = \\ & p\& \\ & 2 \\ & eq \\ & vp \\ & 1 \\ & \& = vp \\ & yy \\ & xx \\ & 2 \end{aligned}$$

$$\begin{aligned} & - R - N \\ & eq \\ & C \\ & with \\ & p\& = \end{aligned}$$

$$\begin{aligned} & where \\ & = \end{aligned}$$

$$\begin{aligned} & R \\ & R p \\ & 0 \\ & if \\ & : \\ & p\& = 0 \\ & vp \\ & \& = 0 vp \\ & \& = 0 vp \\ & eq \\ & C \\ & xx \\ & xy \\ & \&yy = 0 \end{aligned}$$

Lastly, the total deflection is:

$$\begin{aligned} & = E \\ & vp \\ & xx + \\ & xx \\ & xx \end{aligned}$$

**=  $E$**   
 **$\nu p$**   
 **$\sigma_y +$**   
 **$\sigma_y$**   
 **$\sigma_y$**

**=  $E$**   
 **$\nu p$**   
 **$\sigma_y +$**   
 **$\sigma_y$**   
 **$\sigma_y$**

*The reference solution is obtained by using a program written in FORTRAN which carries out one resolution step by step of the problem with an implicit diagram of discretization.*

**HSNV120 - Hyperelastic traction**

**of a bar under thermal loading**

**Summary:**

*This quasi-static thermomechanical test consists in heating a parallelepipedic bar uniformly, it to subject to an important traction for finally letting it return in a discharged state. One validates thus kinematics of the great hyperelastic deformations (order STAT\_NON\_LINE, key word COMP\_ELAS) for a relation of elastic behavior non-linear (ELAS\_VMIS\_LINE and ELAS\_VMIS\_TRAC) with thermal loading.*

*The bar is modelled by a voluminal element (HEXA20, modeling A) or quadrangular (QUAD8, assumption of the plane constraints, modeling B).*

*The results obtained by Aster do not differ from the theoretical solution.*

The relation of behavior is written:

2  
 $S$   
 $= K$

$xx$   
(+  $B$  *has*  
2) +  $G$  (*has* -  $b$ )

3

1

 $S$  $= S$  $= K$  $yy$  $zz$  $(+ B \text{ has}$  $2) - G (\text{has} - b)$ 

3

with:

 $E$  $3K = 1-2$ 

modulate compressibility

To determine  $G$  by taking account of linear work hardening, one introduces: $E$ · the modulus of rigidity:  $2\mu = 1 +$  $E E$ · the module of work hardening:  $R$  $T$  $'= E -,$ 

AND

The “pseudo variable interns”  $p$  is worth then: $2\mu (\mathbf{EM})$  $y$  $-$  $y$  $eq$  $2\mu (\text{has} - b) -$  $p =$  $=$  $R' + 3\mu$  $R' + 3\mu$ Finally,  $G$  is written: $y$  $+ R' p$  $G =$  $- B \text{ has}$ 

By taking account of the boundary conditions:

$F$   
 $S_{xx} =$   
(dead load)

$1 + U$   
 $S_{yy} =$

0 (free edge)  
The system to be solved is written:

$2$   
 $2\mu_{has} - B$   
 $y$   
 $-$   
 $F$   
 $K (has + B$   
 $2 )$   
 $($   
 $)$   
 $y$   
 $+ + R'$   
 $=$   
 $3$   
 $R$

$' + 3\mu$   
 $1 + U$

$1$   
 $2\mu_{has} - B$   
 $y$   
 $-$   
 $K (has + B$   
 $2 )$   
 $($   
 $)$   
 $y$   
 $-$

$$+ R'$$
$$= 0$$
$$3$$
$$R$$

$$' +$$

$$3\mu$$

*Handbook of Validation*

*HI-75/96/030/A*

---

**Code\_Aster** ®  
*Version*  
*3*  
*Titrate:*  
*HSNV120 - Hyperelastic traction of a bar*  
*Date:*  
*21/05/96*  
*Author (S):*  
**E. LORENTZ**  
*Key:*  
*V7.22.120-A Page:*  
*6/12*  
It is also written:

$$F$$
$$3K (+ 2b \text{ has}) =$$

$$1+ U$$

$$F$$
$$3\mu$$
$$3$$

$$\mu$$
$$2 (\text{has} - b) =$$
$$1$$
$$y$$
$$+$$
$$\mu$$

1

+  $U$

$R'$  -

$R'$

WITH  $F$  fixed, it is thus about a nonlinear system out of  $U$  and  $v$ , since  $A$  is quadratic out of  $U$  and  $B$  quadratic in  $v$ .

Nevertheless, one can choose to fix  $U$  (thus *has*) and to solve a linear system out of  $F$  and  $B$  (of which one

deduced  $p$  and  $v$ ):

(

$U U + 2$ )

.

*has* =

-  $T$

2

1  $F$  -6  $K B = 3$

$K$  *has*

1+  $U$

.

3 $\mu$

1

3

$\mu$

1+

$F + 2\mu B = 2$

$y$

$\mu$  *has*

$R'$

+

1

+  $U$

$R'$

$$2\mu (has - b)$$

$$y$$

$$-$$

$$\cdot$$

$$p =$$

$$R' + 3\mu$$

$$\cdot$$

$$v =$$

$$1 + ($$

$$2 B + has T$$

$$) - 1$$

It then remains to express the constraint of Cauchy:

$$=$$

$$1$$

$$\mathbf{F} \mathbf{S} \mathbf{F} \mathbf{T}$$

$$\text{Det}(\mathbf{F})$$

That is to say here:

$$1 + U$$

$$xx =$$

$$($$

$$S$$

$$1 + v) 2 xx$$

$$yy = zz =$$

$$0$$

As for the force exerted on the face [3,4], because of assumption of died loads, she is written simply:

$$F$$

$$X = F So$$

where So: initial surface of the face [3,4]

$$F$$

$$y = 0$$

$$F$$

$$Z = 0$$

## Results of reference

One will adopt like results of reference displacements, the constraint of Cauchy and the force exerted on the face [3,4] (in 3D only):

**At time  $T = 2$  S** ( $T = 100^\circ\text{C}$ , traction  $F$ )

In fact, one seeks  $F$  such as lengthening:

$U = 0.1$

,

.

$K = 166.666 \text{ MPa}$   $\mu = 76.923 \text{ MPa}$   $R' = 2.020 \text{ MPa}$

.

$= 0.095$  have

0.90909

$F - 106 B = 47.500$

$104.76 F + 153.85 B = 128.85$

.

$F = 1.298 \text{ MPa}$

$B = -$ .

0.046

.

$p = 8.91 \cdot 10^2$

.

$v = -3.70 \cdot 10^2$

9

$xx$

$= 1399.66 \text{ MPa}$

$xy = 0$

$$F_x = 1.298 \text{ 10 NR}$$

.

$$y_y = 0$$

$$x_z = 0$$

$$F_y = 0$$

$$z_z = 0$$

$$y_z = 0$$

$$F_z = 0$$

**At time  $T = 3 \text{ S}$  ( $T = 0$ ,  $F =$ )**

0

The bar returned in its initial state:

**U**

$$= 0$$

$$= 0$$

$$p =$$

0

## 2.3

### Uncertainty on the solution

The solution is analytical. With the rounding errors near, one can consider it exact.

## Summary of the results

The numerical and analytical results coincide remarkably. One can however be astonished by execution time manifestly longer for modeling in plane constraints (123,8 S) that for the 3D (47,2 S). The difference is explained by a discretization in time much finer for plane constraints, related to problems of convergence (the algorithm of resolution of the equation nonlinear scalar out of  $p$  is still rudimentary).

*plastics of a bar under loading*

*thermics*

*Summary:*

*This quasi-static thermomechanical test consists in heating a bar of rectangular section uniformly (3D) or cylindrical (axisymmetric 2D) then to subject it to a traction. One validates the kinematics thus of*

*great deformations in plasticity (order STAT\_NON\_LINE, key word deformation: “SIMO\_MIEHE” or “PETIT\_REAC”) for a relation of behavior in great deformations with isotropic work hardening*

*linear (order STAT\_NON\_LINE, key word relation : “VMIS\_ISOT\_LINE” and “VMIS\_ISOT\_TRAC”) with thermomechanical loading. With modelings hull or plate, them great deformations in plasticity are accessible thanks to the key word deformation: “PETIT\_REAC” provided that rotations remain weak.*

*The bar is modelled by a voluminal element (HEXA20, modeling A) or quadrangular (QUAD4, for an axisymmetric modeling, modeling B) or by elements of plate or hull (DKT for modeling C and COQUE\_3D for modeling D).*

*The solution is analytical.*

## ***11 Summary of the results***

***Results found with Code\_Aster and deformation: “SIMO\_MIEHE” are very satisfactory***

*with percentages of error lower than 0.4% on the constraint and 1.2% on the variable of work hardening. For elements of plate and hull the use of deformation: “PETIT\_REAC” gives satisfactory results with percentages of error of 3% on the effort or the constraint and lower than 0.7% on the variable of work hardening.*

*HSNV122 - Thermoplasticity and metallurgy*

*in great deformations in simple traction*

**Summary:**

*One treats the determination of the mechanical evolution of a cylindrical bar subjected to thermal evolutions*

*and metallurgical known and uniform (the metallurgical transformation is of bainitic type) and with one*

*mechanical loading of traction.*

*The relation of behavior is a model of plasticity in great deformations (order*

*STAT\_NON\_LINE, motclé DEFORMATION: “SIMO\_MIEHE”) with linear isotropic work hardening and plasticity*

*of transformation (order STAT\_NON\_LINE, motclé RELATION: “META\_EP\_PT”).*

*The yield stress and the slope of the traction diagram depend on the temperature and the composition metallurgical. The dilation coefficient depends on the metallurgical composition.*

*The bar is modelled by axisymmetric elements.*

*The mechanical loading applied is a following pressure.*

*This case test is identical to the case test HSNV101 (modeling B, [V7.22.101]) in the direction where it is about same*

*material, of the same loading and the same thermal and metallurgical evolutions but in a version*

*in great deformations.*

*6/12*

*2.2 Notice*

*In the case test HSNV101 (modeling B), the coefficients of material were selected of such manner not to have traditional plasticity “ $p = 0$  during the metallurgical transformation which takes place*

*between moments 60 and 122s. Indeed if one writes the criterion of chargedécharge in this interval of time, one obtains*

*$F = - 2750 p$*

*- 250 with =*

**360 MPa**

*who cancels only for only one value of the cumulated plastic deformation  $p$ .*

*For the law of behavior written in great deformations, the criterion of chargedécharge is written between these two moments*

$$F = J(T) - 2750 p$$

*- 250 with =*

**360 MPa**

*In this case, as long as the variable  $J$  remains lower than the value obtained at time  $T = 60s$ , one will have*

*“ $p = 0$ . However the value of  $J$  is a function only of the value of the thermal deformation (constraint is constant and the coefficient  $K$  is independent of the metallurgical phases and of temperature).*

*In this interval of time, thermal deformation  $HT$  is given by the following equation:*

$$HT =$$

*-7*

*$T^2$*

*-*

*-4*

*$T -$*

*-*

*8173 10*

*11807 10*

*2 90763 10 3*

*.*

*.*

*.*

*One traces cidessous the thermal deformation as well as the variation of volume  $J$ , solution of the equation of the 3rd degree, according to time.*

Time (S)

agraf 08/11/1999 (c) EDF/DER 1992-1999

*Variation of volume J according to time*

*It is noted that the variable J decreases and increases same manner as the deformation thermics. In this case, to know the moment from which the variable J is higher than the value obtained at time 60s, it is enough to know the moment for which the thermal deformation is identical with that obtained at time  $T = 60s$ . One finds by the resolution of the equation cidessus  $T = 84.46s$ .*

2.3

*Uncertainty on the solution*

*The solution is analytical. Two errors are made on this solution. The first door on calculation of the bainitic proportion of phase created. Preliminary metallurgical calculation does not restore*

*exactly the equation of [§1.2] giving Z fbm according to time, this is why results of reference presented cidessous is calculated with the bainitic proportion of phase calculated by Code\_Aster.*

*The second error is the assumption made on the constraint of Kirchhoff which is not constant on the interval of time ranging between 60 and 176s. This will impact the calculation of ux displacement and of*

*plastic deformation G P.*

2.4

*Results of reference*

*One will adopt like results of reference displacement in the direction of the loading of traction, the constraint of Cauchy, the Boolean indicator of plasticity and plastic deformation cumulated p. the various moments of calculations are  $T = 47, 48, 60, 83, 84, 85$  and 176s. For the calculation of*

*displacement, the initial length of the bar in the direction of loading is of 0.2m.*

**Summary of the results**

**The results found with *Code\_Aster* are very satisfactory with percentages of error lower than 0.9%, knowing that the analytical solution of reference makes the dead end on certain aspects**

what precisely takes into account the solution of *Code\_Aster*. This can explain the differences observed.

## ***Problem of reference***

***It is about a cylindrical bar in creep.***

### ***1.1 Geometry***

***y***

***F=25 NR***

***O***  
***X***

***Appear 1.1-a: Geometry and loading of the problem of reference***

***It is about a cylinder H= height 1.0 m, and ray R=1.0 Mr.***  
***The square in fat corresponds to axisymmetric modeling used to [§3].***

### ***1.2***

#### ***Material properties***

***The properties materials are described by the following parameters:***

***For thermo-metal calculation***  
***(Zircaloy)***  
***CP = 2000000 J.m-3.°C-1***  
***= 9999.9 W.m-1.°C-1***

***Coefficients for the metallurgy:***

***teqd = 809 °C, K=1.135E-2, n=2.187***

***CCT = 831 °C, qsr = 14614, ac = 1.58E-4***

***m = 4.7, tdr = 949,1°C, Ar = -5.725, Br = 0.05***

***For calculation thermo-metal-worker-mechanics***

***• Modulus Young: E= 200000 Pa***

***• Poisson's ratio: = 0.3***

***Definition of the elastic characteristics, dilation and elastic limits for modeling of an undergoing material of the metallurgical transformations:***

***• Tref= 800°C***

***• Thermal Dilation coefficient average of the cold phases:  $F(T) = 0$***

***• Thermal Dilation coefficient average of the hot phase:  $(T) = 0$***

***• Température of definition of the dilation coefficient:  $T = 800°C$***

***• Choix of the metallurgical phase of reference: heat***

***• Déformation of the phase not of reference compared to the phase of reference to Tref temperature: = 0***

***• Limit elastic of the cold phase 1 for a viscous behavior:  $F_{\text{sigm}_f}(T) = 0$***

***• Limit elastic of the cold phase 2 for a viscous behavior:  $F_{\text{sigm}_f}(T) = 0$***

***• Limit elastic of the hot phase for a viscous behavior: to see [Figure 1.2-a]***

***HSNV129 - Test of compression-dilation for  
study of the coupling thermics-cracking***

***Summary:***

*One applies to an element of volume obeying the law of Mazars (local and not-local version) a loading thermomechanical in order to check the good taking into account of the dependence of the parameters materials with the temperature as well as the taking into account of thermal dilation. The loading is homogeneous and also break up: compression with imposed displacement and constant temperature, then application of a cycle of heating-cooling.*

## ***Problem of reference***

### **1.1**

#### ***Geometry and boundary conditions***

*Element of volume materialized by a unit cube on side (m):*

Z

F

G

E

y

B

C

With

D

X

#### ***Appear 1.1-a: Geometry***

*The loading is such as one obtains a uniform stress and strain state in volume.*

*Blockings are as follows:*

*face ABCD:  $DZ = 0$ .*

*face BCGF:  $DX = 0$ .*

*face ABFE:  $DY = 0$ .*

*face EFGH: displacement  $U_z(T)$*

*The temperature  $T(T)$  is supposed to be uniform on the cube; the temperature of reference is worth  $0^\circ\text{C}$ .*

*$U_z$  and  $T$  vary according to time in the following way:*

***moment  $T$***

*0 100 200 300*

***$U_z(T)$***

*0 Mr.*

*103 Mr.*

*103 Mr.*

*103 Mr.*

***$T(T)$***

*$0^\circ\text{C}$   $0^\circ\text{C}$*

*200*

*$^\circ\text{C}$*

*$0^\circ\text{C}$*

*A purely mechanical loading is thus carried out, then one heats by blocking the  $U_z$  direction, before cooling. This makes it possible to check the separation of the thermal and mechanical deformations*

*as well as the non-recouvrance of the mechanical properties after heating.*

## ***1.2***

**Note:**

· *A a given state, the parameters materials used are those defined in the temperature maximum sight by material and not at the current temperature.*

· *The evaluation of the damage  $D$  utilizes the concept of maximum reaches with the course*

history of the loading; the solution is thus not completely analytical but imply a discretization. If there is no influence of thermics, it is enough to take  $\sim$  equivalent with the maximum equivalent deformation reached. When one takes into account the thermal aspect, the heating can contribute “to decrease” or “to delay” the damage with deformation given; it is the case with the evolution of  $B_c$  reserve. In this case, it is necessary in makes rather finely discretize the loading to have the good value of damage  $D$  (which presents indeed a maximum in our case).

## **Summary of the results**

*One obtains the analytical solution with a precision lower than 0.02% what makes it possible to be ensured of*

*good establishment of the model of Mazars including when the temperature intervenes. Let us point out them*

*choices which were made for the coupling cracking-thermics and which are checked here:*

- linear thermal dilation,*
- evolution of the damage only under the effect of the elastic strain and not thermics,*
- dependence of the parameters materials with the maximum temperature, i.e. not reversibility of the modifications of the mechanical properties when the concrete is heated then cooled.*

## **Reference solution**

*One does not have an analytical solution for the calculation of the propagation of a network of cracks in tire thermomechanical. Consequently, this case test is a case test of nonregression. The reference is consisted results resulting from version 7.0 of Code\_Aster.*

### **2.1**

#### **Method of calculation of reference**

*Methodology used to deal with the problem of propagation of two-dimensional cracks in tiredness relates to a calculation 2D plane or axisymmetric which takes into account a radial or axial cut*

*studied tube. This methodology allows the analysis of the propagation of the cracks in the thickness. The present study consists in testing a numerical procedure of simulation of the propagation of cracks in 2D or axisymmetric [bib1]. It is about a method based on automatic mending of meshes to simulate the propagation of the cracks and a strategy of propagation in a network of cracks in fatigue thermal.*

*The procedure of mending of meshes is led with GMSH which launches out automatically after each step*

*of propagation of the cracks to remake the grid during calculation. Strategy of propagation of network of cracks is controlled by increments over the lengths of the cracks. The kinetics of propagation of the fatigue cracks can be described by a law of propagation in fatigue of the type Paris. Within the framework of this modeling, a law of propagation of Paris modified (Pellas and Al [bib2]) which takes into account the effect of the threshold of nonpropagation, the report/ratio of load and tenacity material, is used.*

*By considering a theoretical increment length for all the cracks of the network, one finds fissure which needs the minimum of a number of cycles to be propagated by considering the amplitude of*

*stress intensity factor manpower and the law of propagation. By applying this number of cycles to structure, one finds the propagation of each crack.*

### **2.2**

#### **Results of reference**

*For three stages of propagation, the amplitude of stress intensity factor manpower ( $K_{EFF}$ ) for*

*the dominant crack and the number of cycles of the stage are compared with the values of reference. These*

**values are:**

**Stage 1:**

**(K**

**EFF) = 0.0513, Nétape = 212900**

**Stage 2:**

**(K**

**EFF) = 0.0550, Nétape = 178574**

**Stage 3:**

**(K**

**EFF) = 0.0613, Nétape = 135107**

#### ***The law of propagation***

***The propagation of the fatigue cracks follows a law of the Paris type. Within the framework of tiredness to large a number of cycles, the threshold of nonpropagation of crack, the report/ratio of load and the tenacity of material can influence the propagation velocity of the cracks. In this case, the law of propagation of the cracks can be written like a law of Paris amended (Pellas and Al (1977) [bib2] and Yaacoub Aga and Al (1998) [bib3]).***

## **Problem of reference**

### **1.1 Geometry**

One places oneself within the framework of a dimensional mono problem in Cartesian co-ordinates.  
“structure” considered, is finally a segment length  $l$

$$p = 0$$

$$p = P$$

$$X = l$$

$$X = 0$$

$$T = l$$

$$T = 0$$

### **1.2**

## **Boundary conditions and loadings**

*One imposes a pressure varying  $P$  in  $X$  linearly = 0 to 0 in  $X = 1$ :  $p(X) = P(1 - X)$*

*In  $X = 0$ : the temperature is imposed null*

*In  $X = 1$ : the temperature is imposed on 1.*

### **1.3 Conditions**

#### **initial**

*$T(X) = 0$  everywhere*

*One is interested in steady operation*

## **2**

### **Reference solution**

#### **2.1**

##### **Method of calculation**

*One leaves the equation of the energy [éq 3.1.3-1] of the document [R7.01.11], which in this case give:*

*$m$*

*$H +$*

*$Q + \text{Div}$*

*$\& \&$*

*$(M$*

*$H) + \text{Div}(\mathbf{Q}) = 0$*

**éq**

**2.1-1**

*In which  $H$  indicates the enthalpy of water,  $\dot{M}$  its flow mass,  $m$  the mass water contribution and  $Q$  heat flow.*

*Taking into account the made assumptions, one sees easily that:*

$$\dot{M} = M = P$$

**éq 2.1-2**

$X$

$W H$

$$H = C P t$$

**éq 2.1-3**

$W$

$T$

$$Q = Q = -$$

**éq 2.1-4**

$X$

$T$

$X$

$$Q = C P t$$

&

**éq 2.1-5**

$W$   
 $W$  &  
 $K$   
*is the thermal coefficient of diffusion process,*  
 $int$   
 $=$   
*is the hydraulic coefficient of diffusion,  $K$*   
 $T$   
 $H$   
 $\mu$   
 $int$   
 $W$   
*the intrinsic permeability,  $\mu$ ,  $p$*   
 $C$  *are respectively the density, viscosity and*  
 $W$   
 $W$   
 $W$   
*calorific heat with constant pressure of water.*

While deferring [éq 2.1-2], [éq 2.1-3], [éq 2.1-4] and [éq 2.1-5] in [éq 2.1-1] one finds:

$p$   
 $2$   
 $C$   
 $W$   
 $W$   
 $p$   
 $H$   
 $T$   
 $T + C$   
 $P$   
&

**éq**

**2.1-6**

*W*

*W*

-  $T = 0$

2

*T*

*T*

*X X*

*One poses:*

$R = C_p H P$

*W*

*W T*

*and*

*p*

$w C w$

$S =$

*T*

*One obtains*

2

*T*

*T*

$S \& + R$

-  $T = 0$  **éq**

**2.1-7**

2

*X X*

### *1.3.2 Modeling coupled with hydraulics*

*Phase 1:*  
One brings the sample in a homogeneous state of effective stresses: 0  
0  
0  
 $xx = yy = zz$ , while imposing  
corresponding total pressure on the front, side right-hand side and higher faces and while imposing  
everywhere null water pressures. Displacements are blocked on the faces postpones ( $ux = 0$ ),  
side left ( $U_y = 0$ ) and lower ( $uz = 0$ ).

**Phase 2:**

*One maintains displacements blocked on the faces postpones ( $u_x = 0$ ), side left ( $u_y = 0$ ) and lower ( $u_z = 0$ ).*

*On all the faces, hydraulic flows are null.*

*One applies a displacement forced to the higher face in order to obtain a deformation  $zz = -20\%$  (counted starting from the beginning of phase 2). On the front faces and side right-hand side, one*

*impose boundary conditions in total constraint:*

$$.n = 0 \text{ (= 100kPa)}$$

**2**

**Reference solution**

**2.1**

**Reference solution for the water pressure into linear**

**0, 0  $p_0$  indicating the constraints, water deformations and pressures obtained in the phase one a:**

$$-0 = tr(-0) + 2\mu(-0) - ($$

$$B p - 0$$

$$p)$$

$$m$$

$$p - p$$

$$=$$

$$0 + btr$$

*fl*  
( -0)

*M*  
*l*  
In this writing, *M* indicates the module of biot and *NR* =

·  
*M*  
The boundary conditions of null flow and the conservation of the water mass give  $m = 0$   
Boundary conditions on the side walls and the fact that the state of stress is homogeneous give:

$$xx - xx = 0$$

$$0$$

One has thus finally to solve the two equations:

$$(2$$

$$xx +$$

$$zz) + 2\mu$$

$$xx = LP$$

$$($$

$$p$$

$$B^2$$

$$xx +$$

$$zz) = -$$

$$= - Np$$

*M*  
And one obtains:

$$2$$

$$zz$$

$$B + NR$$

$$xx = -$$

$$2b^2 + (+\mu) NR$$

$\mu$   
 $B_{zz}$   
 $p = -$

$b_2$   
 $+ (+\mu) NR$

*In our case,*

$zz$   
 $xx = -$   
 $;$   
 $p = -$   
 $\mu_{zz}$   
 $2$

2.2  
*Development of analytical solution CJS*

*One has permanently:*  
 $zz$   
*for the deformations:*  $xx = yy = -$

$2$   
*for the constraints:*  $xx = yy$

*Elastic phase:*  
*While writing the elastic law simply, it comes:*

$0$   
 $xx = xx - \mu_{zz}$

$0$   
 $zz = zz + 2\mu_{zz}$

*One also has according to the elastic law:*

*trans*

*trans*

*xx = xx*

+

*xx and zz = zz +*

*zz*

*where:*

*D*

*D*

*D*

*D*

*D*

*D*

*D*

*D*

*D*

$$xx = 2 \mu (xx - Gxx) + (v - tr (G) = - \mu zz - 2 \mu Gxx - (2 Gxx + Gzz)$$

*D*

*D*

*D*

*D*

*D*

*D*

*D*

*D*

*D*

$$zz = 2 \mu (zz - Gzz) + (v - tr (G) = 2 \mu zz - 2 \mu Gzz - (2 Gxx + Gzz)$$

*and with:*

*trans*

*trans*

*xx = xx - xx*

*and zz = zz - zz*

*maybe, according to what precedes, one has for sII:*

**2**

**S**

**trans**

**trans**

**trans**

**D**

**D**

**D**

**II = -**

**3 μ**

**2 μ**

**3 [(zz**

**- xx) +**

**(zz - zz) -**

**(G - G**

**zz**

**xx)]**

**2**

**= strans**

**trans**

**D**

**D**

**D**

**II**

**-**

**3 μ**

**2 μ**

**3 [**

**(zz - zz) -**

**(G - G**

**zz**

**xx)]**

**and for II:**

**I = I trans - (+ μ)**

**D**

$(Gd + Gd$   
 $1$   
 $1$   
 $3$   
 $2$   
 $2 \, xx$   
 $zz)$

*One deduces from it that the function of load déviatoire is written:*

$1/6$   
 $2$   
 $F \, D = strans$   
 $trans$   
 $D$   
 $D$   
 $D$   
 $1/6$   
 $II$   
 $(1- ) -$   
 $3 \, \mu$   
 $2 \, \mu$   
 $1$   
 $3 [$   
 $(zz - zz) -$   
 $(G - G$   
 $zz$   
 $xx)] (-)$   
 $+R \, I \, trans$   
 $1$   
 $- R$   
 $D$   
 $D$   
 $D$   
 $m$   
 $m (3 + 2 \, \mu)$

$(2 \, G + G$   
 $xx$   
 $zz)$   
*By taking account of the fact that  $F \, D$  (trans*

) =0, one finds then for the plastic multiplier:

$$3 \mu \frac{1}{6}$$

$D$

( )

=

(trans

zz - zz

)

3

$2 \mu (D$

$D$

$D$

$D$

$G_{zz} - G_{xx}) -$

$Rm (3 + 2 \mu) (2 G_{xx} + G_{zz})$

### ***Summary of the results***

*The values of Code\_Aster are in perfect agreement with the values of reference. Concerning coupling with hydraulics, this test proves that by means of computer, coupling CJS/THM functions and that the equations of hydraulics are at least able to give again the null variation of volume when water is incompressible.*

***V7.31 booklet: Mechanical hydro Thermo in porous environment of voluminal structures***

***Document: V7.31.101***

***WTNV101 - Triaxial compression test not drained with the model  
of Laigle and with hydraulic coupling***

***Summary***

***This test makes it possible to validate the model of Laigle with hydraulic coupling. It is about a triaxial compression test in not drained condition. The aspect not drained is modelled by a null voluminal deformation of the skeleton and it hydraulic coupling is taken into account, the sample is completely saturated, the skeleton and the fluid being presumed incompressible. By reason of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test. The level of containment is 8 MPa.***

***WTNV107 - Subjected saturated porous surface  
with a thermohydraulic shock***

***Summary:***

*One considers a surface problem (in 3D) of behavior of a saturated porous environment subjected to one thermohydraulic loading.*

*One studies a transient state, for the problems of coupled thermohydraulic diffusion (however the part mechanics does not intervene, indeformable porous surface).*

*The model is 3D surface, with a linear thermohydraulic behavior for modeling 3D\_JOINT\_CT.*

*The test validates in particular the taking into account of the curve of surface (portion of cylinder).

**2**

***Reference solution***

**2.1**

***Method of calculation used for the reference solution***

*In the absence of voluminal forces, the hydrothermal system of coupled equations is written (for one nonheating material) (being the surface Laplacian):*

· *thermal equation of evolution*

$C_0 T$

$P$   
 $T T =$   
 $- 3$   
 $R$

$T$

$m$   
 $T$   
 $T$

· *hydraulic equation of evolution*

$1 P$

$T$   
 $H P =$   
 $- 3$

$M$   
 $m$   
 $T$   
 $T$

*By choosing the boundary conditions identical for the two problems, and of the coefficients such that the equations are identical one brings back to the solution of only one equation:*

$C$

$0$   
 $T$   
 $T$   
 $3$   
 $T$   
 $=$   
 $-$   
 $Tr$   
 $m T$

$P = T$  and

$l$

$C$

with

and

$0$

$T = H$

$=$

$M$

$Tr$

*It is an equation of the diffusion type of the heat defined on a surface.*

*One chose a cylindrical surface, the problem depends only on the angle (unidimensional problem of diffusion).*

*One can seek solutions by separating the variables (space and time), which gives a solution in product the exponential ones of the time and cosine of the variable of space.*

*To check the initial conditions, one obtains a development in series (resolution semi-analytical problem).*

***WTNV122 - Triaxial compression test not drained with the law  
CAM\_CLAY***

***Summary:***

*This test makes it possible to validate the mechanical law elastoplastic Cam\_Clay specific to the grounds normally consolidated. This law integrates an elastoplastic hydrostatic mechanism (of which the elastic part is non-linear and the threshold of flow corresponds to the pressure of consolidation) coupled to a deviatoric elastoplastic the elastic part is linear. The behavior is hardening or*

*softening according to the combination of the two mechanisms.*

*Three different modelings are carried out in 3D. In each modeling, the test is carried out in hydro-mechanical coupling and it include/understand two ways of loading:*

*Modeling A is characterized by:*

*.  
a hydrostatic way of compression in condition drained until the pressure of consolidation,*

*.  
a way not-drained by maintaining the pressures lateral confining on the sample and by imposing one vertical displacement of compression which induces a triaxial state of stresses, and a plastic mode contractor.*

*Modeling B is characterized by:*

*.  
a hydrostatic way of compression in condition drained until the critical pressure, equalizes with half of the pressure of consolidation,*

*.  
a way not-drained by maintaining the pressures lateral confining on the sample and by imposing one vertical displacement of compression which induces a triaxial state of stresses up to the critical point.*

*Modeling C is characterized by:*

*.  
a hydrostatic way of compression in condition drained until a pressure lower than critical pressure,*

*.  
a way not-drained by maintaining the pressures lateral confining on the sample and by imposing one vertical displacement of compression which induces a plastic state of stresses triaxial dilating.*

$= 0.3$

$= 1.E - 5$

Parameters specific to CAM\_CLAY:

$PORO = 0.14, = 0.25, = 0.05, M = 0.9, CLOSE\_CRIT = .$

$3 E5 Pa, Pa = 1.E5 Pa$

**1.3**

**Boundary conditions and loadings**

*The first way of loading is carried out with a state of hydrostatic stresses:*

*$\sigma_x = \sigma_y = \sigma_z = P$ . One makes a first elastic design to  $P = P_a$  (to establish an initial state*

*$\sigma_x$*

*$\sigma_y$*

*$\sigma_z$*

*plastically acceptable). One increases then  $P$  to  $P$ , the pressure of water is maintained*

*$\sigma_x$*

*$\sigma_y$*

*$\sigma_z$*

*$P_{eff} = 0$  (drained condition). For the second way, one maintains the pressure  $P$  on the faces*

*side and one imposes then a vertical displacement imposed in compression to model one*

*triaxial compression test, calculation is now not drained, which corresponds to a hydrostatic flow no*

*one on*

*all faces.*

*For modeling a:  $P$*

*$\sigma_x = P$*

*$\sigma_y = P$*

*$\sigma_z = 6 \times 10^5 \text{ Pa} = 2P$  (final state contracting)*

*$\sigma_x$*

*$\sigma_y$*

*consolidat*

*$\sigma_z$*

*For modeling b:  $P$*

*$\sigma_x = P$  (final state criticizes with null voluminal variation)*

*$\sigma_y$*

*$\sigma_z$*

*For modeling C:  $P$*

*$\sigma_x = P$*

*$\sigma_y = 2 \times 10^5 \text{ Pa} < P$  (final state dilating)*

*$\sigma_z$*

*$\sigma_x$*

## **1.4 Conditions**

### **initial**

*The plastic condition of compatibility requires that in an initial state the hydrostatic constraint be*

*strictly higher than zero. To initialize this constraint, one chose to carry out at the beginning a*

*calculation*

*purely elastic while making evolve/move pressure of 0. with  $1 \times 10^5 \text{ Pa}$ . One only extracts from this*

*calculation*

*the stress field at the points of gauss. This stress field resulting from the elastic design is*

*regarded as the initial state of the hydrostatic constraint necessary to the law Cam\_Clay of calculation*

*according to.*

### **Summary of the results**

*tr ()*

*By interpreting the diagram, (P, Q), P = -*

*and Q = - (-) for three modelings of*

3

3

1

*this case test, one notes well that in modeling A [Figure 6-a], the loading remains hydrostatic up to a value of 6.E5Pa. Once vertical displacement is imposed and vary with time, the pressures on the side faces being maintained constant, a diverter constraints is induced and increases with time with a positive work hardening. When one bring closer the point Q = MP, one tends towards perfect plasticity with plastic flow without work hardening and without variation of constraints (see [§6] Doc. [R7.01.14]).*

*MP*

*Q =*

**Appear 6-a: Q according to P (modeling A)**

*In modeling B [Figure 6-b], after a hydrostatic loading which reaches the critical pressure with 3.E5Pa, the second loading is only deviatoric with a hydrostatic pressure maintained with 3.E5Pa. When one reaches the point criticizes, one touches the critical slope, where plasticity is*

*perfect with plastic flow without work hardening and variation of constraints.*

***WTNV123 - Triaxial compression test with suction fixed with  
model of Barcelona***

***Summary:***

***This test makes it possible to validate the model of Barcelona, which integrates an elastoplastic mechanical law coupled to hydraulics (and possibly with thermics) in condition of nonsaturation of the liquid phase. This law integrate an elastoplastic hydrostatic mechanism (of which the elastic part is non-linear and the threshold of flow corresponds to a pressure of variable consolidation with suction) coupled to a mechanism deviatoric elastoplastic. The characteristics of these mechanisms depend on suction (i.e. difference between gas pressure and pressure of liquid). There are in particular two mechanisms***

*of work hardening in completely coupled pressure and suction. the surface of load of the model of Barcelona*

*present (in the diagram pressure hydrostatic-diverter and for a given suction) in the form of an ellipse cutting the hydrostatic axis in two points: the value of the pressure of consolidation and cohesion of material proportional to suction. In condition of complete saturation, this criterion is reduced to*

*that of the Cam\_Clay model specific to the saturated normally consolidated grounds.*

*This test carried out in hydro-mechanical coupling (modeling HHM) is declined in three modelings:*

*Modeling A includes/understands two ways of mechanical loading, suction being fixed at a value correspondent with a degree of saturation of 90%:*

*1) a hydrostatic way of compression*

*2) a way maintaining the pressures lateral confining on the sample and imposing a vertical pressure additional which induces a triaxial state of stresses, until reaching the surface of load and to generate plastic deformations in the contracting field.*

*Modeling B takes again modeling A but with a criterion of convergence of balance on each generalized constraint.*

*Modeling C continues modeling B by a deviatoric discharge then hydrostatic conclusive by a deviatoric refill plasticizing in the dilating field.*

*All these modelings are carried out in 3D on an element hexaedric.*

## ***WTNV124 - Test of désaturation-consolidation with the model of Barcelona***

### ***Summary:***

***This test makes it possible to validate the model of Barcelona, which integrates an elastoplastic mechanical law coupled to hydraulics (and possibly with thermics) in condition of nonsaturation of the liquid phase. This law integrate an elastoplastic hydrostatic mechanism (of which the elastic part is non-linear and the threshold of flow corresponds to a pressure of variable consolidation with suction) coupled to a mechanism deviatoric elastoplastic. The characteristics of these mechanisms depend on suction (i.e. difference between gas pressure and pressure of liquid). There are in particular two mechanisms of work hardening in completely coupled pressure and suction. The surface of load of the model of Barcelona present (in the diagram pressure hydrostatic-diverter and for a given suction) in the form of an ellipse cutting the hydrostatic axis in two points: the value of the pressure of consolidation and cohesion of material proportional to suction. In condition of complete saturation, this criterion is reduced to that of the Cam\_Clay model specific to the saturated normally consolidated grounds. This test carried out in hydro-mechanical coupling (modeling HHM) includes/understands two ways of loading:***

- 1) a way of desaturation while making increase the capillary pressure beyond the threshold of plasticity hydrous.***
- 2) a hydrostatic way of compression on the désaturé sample.***

***Modeling is carried out in 3D.***

***WTNV127 Désaturation of a porous environment without  
air (modeling 3D\_THV)***

***Summary:***

***One heats a porous environment whose pores are filled with a mixture of water and steam. Saturation initial in liquid is 50%, the loading is a uniform heat flux on the edges of the field.  
modeling made by only one cubic element corresponds to the modeling of a homogeneous problem in space.***

***The reference solution is an approximate analytical solution.***

$\nu p$   
 $l q$   
 $T$

### 2.1.2 Calculation of the temperature

[R7.01.11] equation [éq 3.2.4.3 - 1] gives:

$$\frac{Q}{m} = - T p$$

$$+ \frac{C_0}{3 T}$$

$g z$   
 $\nu p$

éq  
 2.1.2-1  
 (since the other dilation coefficients are null).  
 Equation [éq 3.2.4.3 - 2] gives:

$$1 - \frac{m}{(S l q)} = g z$$

$$\frac{é q}{2.1.2-2} T^3$$

One thus obtains:

$$\frac{Q}{m} = - \left( - S + \frac{0}{1} \right)$$

$$l q) p C T \nu p$$

*éq*  
**2.1.2-3**

*In this problem,  $Q$   
 is anything else only the heat brought per unit of volume.  
 By calling *Flight* the total volume of the part and *Surfing* its side surface and  $T$   
 the time of application  
 flows:

***WTNV128 - Triaxial compression test not drained with the model  
of Hoek-Brown modified in effective constraints***

***Summary***

***This test makes it possible to validate the law of elastoplastic behavior of Hoek-Brown modified in  
constraints***

***effective, that is to say HOEK\_BROWN\_EFF with hydraulic coupling. It is about a triaxial  
compression test in condition not  
drained. The aspect not drained is modelled by a null voluminal deformation of the skeleton and the  
coupling  
hydraulics is taken into account. The sample is completely saturated, the skeleton and the fluid being  
supposed***

***incompressible.***

***For reasons of symmetry, one is interested only in the eighth of a sample subjected to a triaxial compression test.***

***The level of containment applied is 5 MPa.***

***It is about a test of nonregression.***

***Modeling A is a modeling of the 3D\_HM type with integration at the points of Gauss.***

***Modeling B is a modeling of the 3D\_HMS type with integration at the points of Gauss or the nodes (see Doc. [R7.01.10]).***

### ***Summary of the results***

*This case test is a test of not-regression developed to validate the model of Hoek-Brown modified in effective constraints, HOEK\_BROWN\_EFF, with hydraulic coupling.*

*One obtains the same results with two modelings 3D\_HM or 3D\_HMS.*

*Handbook of Validation*

*V7.31 booklet: Thermo-hydro-mechanics in porous environment of voluminal structures*

***V7.31 booklet: Thermo-hydro-mechanics in porous environment of voluminal structures***

***Document: V7.31.129***

***WTNV129 - Triaxial compression test not drained with the model  
of Hoek-Brown modified in total constraints***

### ***Summary***

***This test makes it possible to validate the elastoplastic law of behavior of Hoek-Brown modified in  
constraints***

***total is HOEK\_BROWN\_TOT with hydraulic coupling. It is about a triaxial compression test in not  
drained condition.***

***The aspect not drained is modelled by a null voluminal deformation of the skeleton and the hydraulic  
coupling***

***is taken into account. The sample is completely saturated, the incompressible skeleton and the fluid  
being supposed.***

***For reasons of symmetry, one is interested only in the eighth of a sample subjected to a triaxial  
compression test.***

***The level of containment applied is 5 MPa.***

*It is about a test of nonregression.*

*Modeling A is a modeling of the 3D\_HM type with integration at the points of Gauss.*

*Modeling B is a modeling of the 3D\_HMS type with integration at the points of Gauss or the nodes (see Doc. [R7.01.10]).*

***WTNP104 - Diffusion of air dissolved in water (plan  
THH2M)***

## **Summary:**

*Here a problem at temperature and constant saturation are considered. By boundary conditions suitable one imposes a water pressure and a steam pressure constants. A gas pressure is imposed on one edge of the field (null flows of the other with dimensions). Only pressures of dry air and dissolved air connected by the law of Henry evolve/move. This problem brings back in an equation for the pressure of dry air of type "equation of heat". The reference solution will be then a thermal calculation ASTER. It is exactly about the same case test that the WTNP103 but in modeling THH2M.*

***Summary:***

***The test presented here makes it possible to check the correct operation of the operators used for the resolution of equations of a flow in unsaturated medium. This test corresponds to test 3.2 of the plan of qualification of the project ALLIANCES [bib1].***

***It represents the evolution of water saturation of the medium around an cell of storage. Two phases are takings into account, a phase of desaturation at the time of the exploitation of the underground work and a phase of***

*resaturation after the fill of gallery of the cells.*

### **1.3**

#### ***Initial conditions***

***The problem comprises two phases:***

- First a 15 years phase of desaturation corresponding to the exploitation of the work underground***
- One second phase of resaturation after the fill of the cell corresponding to exploitation (one initializes the saturation of the cell with 0,7).***

***The initial conditions are as follows:***

#### ***For phase 1***

- Alvéole  $P = 9,4.10^7 \text{ Pa}$  ( $S = 0,49$ )***  
***C***
- Geological Barrière  $P = 1.10^5 \text{ Pa}$  ( $S = 0,999$ )***  
***C***

#### ***For phase 2 ( $T > 15$ years)***

- Alvéole  $P = 3,015.10^7 \text{ Pa}$  ( $S = 0,7$ )***  
***C***

### **1.4**

#### ***Boundary conditions***

***They are expressed on the capillary pressure.***

***V7.33 booklet: Thermo-hydro-mechanics in porous environment of structures axisymmetric***

***Document: V7.33.102***

***WTNA102 - Diffusion of dissolved air (axi)***

***Summary:***

*Here a problem at temperature and saturation constants are considered. By boundary conditions adapted one imposes a water pressure and a steam pressure constants. A gas pressure is imposed on an edge of the field (null flows on other side). Only pressures of dry air and dissolved air connected by the law of Henry evolve/move. This problem is brought back in an equation for the pressure of dry air of type*

*“equation of heat”. The reference solution will be then a thermal calculation ASTER.*

## **1 Presentation**

The studied model problem is such as the solution is uniform in space, without any external effort given, so as to test only the treatment of the relation of behavior.

The following solid thus is considered:

· height

$H$ ,

· axisymmetric (of rays  $has$  and  $b$ ),

· or parallelepipedic (thickness  $B$  -  $has$ ).

$Z$

$H$

0

$R$

$has$

$B$

It is placed between two lubricated rigid plates.

The material is thermoelastoplastic homogeneous (see hereafter) with isotropic work hardening and criterion of

Von Mises.

One supposes the uniform temperature spaces some, and increasing.

### **Relation of behavior**

Isotropic, linear work hardening (tangent *AND* constant module).

Criterion of Von Mises.

The elastic coefficients, *E* and, as well as the tangent module *AND* are invariants according to temperature.

The elastic limit varies *there* according to the temperature *T*:

*O*

*O*

*y (T)*

$= y (1 - (St - T))$

(for the temperature range studied, is positive *there!*).

The thermal dilation coefficient is constant.

*AND*

#### 5 Solution

The stress field being uniaxial, one a:

-1 0 0

$D$

$L$

=

0 2 0

3 0 0 - 1

As follows:

$$= \begin{matrix} \epsilon q \\ L \end{matrix}$$

and:

$$-1 \ 0 \ 0$$

$$P$$

$$! \ p$$

$$!$$

$$=$$

$$\operatorname{sgn}(L) \ 0 \ 2 \ 0$$

$$2$$

$$0 \ 0 \ - \ 1$$

The relation of behavior leads to:

$$! \ p$$

$$! \ rr = ! = -$$

$$!$$

$$- \operatorname{sgn}$$

$$L$$

$$(L) + ! \ T = =$$

for the case of the parallelepiped

$$E$$

$$2$$

$$(! \ xx ! \ yy$$

$$)$$

$$1$$

$$! \ zz = 0 =$$

$$!$$

$$L +$$

$$! \ p \operatorname{sgn}(L) + ! \ T$$

$$E$$

From where:

3  
1 -  
2  
!  $rr = ! = ! T +$   
!  $L$   
2  
2nd

!  $p = \operatorname{sgn} ($   
 $L$   
 $L) - !$   
!  
 $T -$   
0  
if  
 $L R (p)$

$E =$   
<

$D$   
 $D$

**5.1 Phase**

**rubber band**

At the beginning of the thermal loading,  $L$  being lower than  $y$ !  $p$  is null.

From where:

!

$$L = -E T; \quad rr = T(1+).$$

As follows:

$$L = -E T$$

(compression  $L < 0$ )

$$rr = (1+) T$$

### **Validity of the elastic solution**

The criterion is:

$O$

$$L(T) - Y(T)$$

$$= E = T - y(1 - S T) 0$$

The criterion is not crossed for  $T = [0, ty]$ , with:

$O$

$T$

$y$

$y$

$$= (E O$$

$$+ S$$

$y$

)

$$y - L$$

$$OY$$

$T$

$$T y$$

At the moment  $ty$ :

$$E O$$

$y$

$$L(ty) = -E + OY S$$

*V7.90.02-A*

*Page:*

*9/10*

**5.2 Phase**

**elastoplastic**

*T* ty. One is on the criterion. Then:

*E - E*

*! p*

Max 0;

*T*

*O*

=

+ *S T*

*E E*

(! sgn

*L*

(*L*)

!

*y*

)

*T*

By admitting that one is “charges some” (! *p* >)

0, then one eliminate! *p* to have:

*E - E*

!

= - *E*!

*T*

*O*

*L*

*T T* + sgn (*L*)

$S_y$

$E \text{ AND}$

then:

$E - E$

$S O$

$y$

$! p$

$T$

$=$

$! T \text{ sgn}$

$(L) +$

$E$

$E$

With  $T = ty$ ,  $L = - E ty < 0$ ; one integrates then these expressions for  $T T (T y! =)$ :

$E - E$

$T$

$O$

$L (T) = - \text{AND} (T - ty)$

$-$

$S_y - L T$

$E E$

$(y)$

$T$

$($

$E - E$

$p T)$

$T$

$=$

$$2$$
$$[E+soy] \ (t-ty)$$

$E$   
Maybe, after rearrangement, ( $T \ ty$ ):

$$E$$
$$T$$

$$O$$
$$T$$

$$1$$
$$1$$

$$L \ (T)$$
$$= y \ S \ T \ - \ +$$
$$-$$

$$E$$
$$T$$

$$y$$

$$O$$

$$y \ (E \ - \ AND)$$
$$T$$
$$p \ (T) =$$
$$-$$
$$1$$

$$E2$$
$$T$$

$$y$$

## Validity of this elastoplastic solution

It should be made sure that  $L(T)$  remains negative. Knowing that  $S T < 1$ , and that  $T > ty$ , the preceding result

confirm that  $L(T) < 0$ .

Lastly, it is noticed that:

1-

2

$\text{sgn}(L)$

$! p + ! rr = (1+)! T$

2

**2**

**Loading of gravity**

**2.1**

**Axisymmetric model 2D**

The density of force is: -  $G \mathbf{e}_z$  (vertical gravity).

One considers the boundary conditions following:

$u_z R$

$(, Z) = 0$  in  $R = R$  and  $Z = 0$

(circle of support)

with uniform traction:  $zz R$

$(, Z) = G L$  in  $Z = L$ , balancing the weight.

One postulates the elastic solution of the type:

0 0

0

= 0 0 0

0 0  $zz$

so that:

$rr = -zz = -uz, Z = -zz;$

$E$

$rz = 0 = R = Z$

One observes as follows:

$ur, R = ur U () = -A' (Z) R$

$R$

$R R, Z$

Then:

$-A' (Z) =$

$()$

$rr = -zz$

$uz, Z R, Z = A' Z$

$()$

$U ()$

$()$

$Z R, Z = A Z + B R$

$()$

From  $rz = 0$ , one draws:

$B R$

$() - R A'' (Z) = 0$

that is to say:

With  $Z$

$() = cste =;$

$B R$

$() = R$

Boundary conditions in effort, one obtains:

$G z^2$

$G r^2$

With  $(Z) =$

$+; B R$

### Axisymmetric model hull

A vertical traction is exerted in  $Z = L$ :

$F = G H L$

Gravity leads to a vertical force:

$\mathbf{F} = - G H \mathbf{e}_z$

The boundary condition on the circle of support is:  $uz, Z$

$() = 0$  in  $Z = 0$

The solution is membranous, vertical balance is written:

$N_{zz}, Z = G H$

Moreover:  $NR = 0$ . In elasticity, one deduces then:

$- NR$

$G Z$

$G$

$E$

$zz$

**FDLV100 - Piston coupled to a column of fluid**

**incompressible**

**Summary:**

This test of the field of the fluids (coupling fluid-structure) validates the calculation of mass added on modal basis and

carry out, within the framework of a modal analysis, the calculation of the Eigen frequency of a system piston-arises

coupled to a column of incompressible fluid. To model the fluid, thermal elements are used

plans; to model the piston, one uses machine elements 2D in plane deformation and an element

discrete to model a spring. Lastly, the fluid interface/structure is modelled by linear elements

thermics modified to introduce a boundary condition of the type “acceleration” into the fluid. The case-test

comprise only one modeling, two-dimensional. The Eigen frequency of the coupled system is found to 0.01% of the analytical result.

### **1.3**

## **Boundary conditions and loading**

One imposes a pressure (IE by analogy thermal a null temperature [R4.07.03]) in all them nodes of the end of the fluid column.

One imposes the embedding of the spring on the solid mass and one imposes a displacement of the null piston according to

OY.

V8.01.100-A Page:

3/6

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

**Analytical calculation:**

When the structure vibrates in the fluid, it modifies the field of pressure which obeys an equation of Laplace with boundary conditions of Von Neuman [R4.07.03].

In our case, taking into account symmetries of the problem, the field of pressure depends only on variable  $X$  and checks:

$2p$

$p$

$=$

$0$

$X$

$N$

$2$

$F$

$S$

X

X

= -

 $X$  $p$ 

=

 $= 0 \text{ in } X = L$ 

One notes as well as the field of pressure is a function closely connected of X-coordinate X. Both boundary conditions on the pressure imply:  $p$

 $= - \rho S \frac{dX}{dt}$  $F$ 

)

The compressive force which is exerted on the structure writes:

 $F$ 

=

 $\rho S D$ 

=

 $L (\rho S D) \frac{dX}{dt}$  $p(0)$  $S$  $D$  $F$ 

As the problem is unidimensional, this force can be expressed in an algebraic way according to component of acceleration according to OX of the structure:

 $F = - X L D = - L D X = - m X \text{ with } m = L D$  $F$  $F$ *has**has* $F$ 

It is the linear mass added of the fluid on the structure: it is noticed that it corresponds to the mass of fluid in the column, i.e. to the mass of fluid moved by the piston.

The equation of the movement of the piston projected on OX is written (free vibration not damped out taking into account

the presence of the fluid):

 $m X + K X$

$$= F = - m X (m + m) X + K X =$$

has

has

0

The Eigen frequency of this immersed system is thus written:

1

$K$

$F$

$$= 2 m + m a$$

The effect of the fluid is thus to lower the Eigen frequency of the system in air.

Practically, in Aster, the matrix of added mass is given on the basis of modal

structure in the vacuum: To calculate the added mass given above, one restricts oneself with the calculation of

clean mode of the system piston-arises which corresponds to a translatory movement normalized with the unit

: one truncates consequently the modal base of the structure to only one mode in air (operator

MODE\_ITER\_SIMULT option PLUS\_PETITE). One determines thanks to this mode the mass added on the piston.

$K$

=

5

10 NR/m

$m$

$$= 200 \text{ kg/m}$$

$m$

=

has

78 kg/m

The Eigen frequency of the system piston-arises immersed is thus  $F$

$$= 3.018 \text{ Hz}$$

**Summary:**

This test of the field of the fluids (fluid coupling/structure) validates the calculation of matrix of mass added in

case where one has several structures immersed in the same fluid.

By a modal analysis, one thus determines the coupled modes of the two structures because of the mass of fluid which separates them. One adopts a modeling planes (thermal for the fluid, and deformation planes for cylinders).

One finds the modes coupled of the system with less than 0.1% of the analytical result.

**Reference solution****2.1****Method of calculation used for the reference solution****Analytical calculation:**

One will suppose that the movements of the cylinders and the fluid are primarily plane. Effects longitudinal will be neglected in front of the transverse effects. The problem is two-dimensional. Count held of symmetry, the reference mark used is a cylindrical reference mark ( $R$ ,) related to the central cylinder (see figure above). In this frame of reference and with this particular geometry, the normal derivative

is equal to the derivative  
compared to  $R$ .

$N$

$R$

In all this part, the variable  $p$  indicates the hydrodynamic field of pressure in the fluid created by the natural vibrations from the structures,  $X_1$  or 2 indicates the clean modes of cylinder 1 or 2 respectively.

Clean modes of the hulls of border (

1) and (2) in the absence of fluid is form ( $N$  indicate the order of the mode):

$\cos$

$N$

or

$\sin N$

0

$1n$

$X$

$(\mathbf{R})$

and

$X^2 N (\mathbf{R})$

0

$\cos N$

or

$\sin N$

is the azimuth angle. These modes are uncoupled of course. The 1st component corresponds to normal displacement of the interior hull, 2nd with that of the external hull. In volume fluid, one has thus two problems to solve:

$\cos N$

$p$

$p$

$1n$

$1n$

$p$

$= 0$

$= -$  or

$= 0$

**éq 2.1-1**

$1n$

$F$

$N$   
 $N$   
 $\sin N$

1  
 2  
 and:  
 $\cos N$   
 $p$

$p$

$2n$   
 2  
 $p$

$= 0$

$= 0$   
 $N$

$=$  or  
**éq 2.1-2**  
 $2n$   
 $F$   
 $N$   
 $N$

1  
 2  
 $\sin N$

The field  $p N$   
 1 corresponds to the field of pressure generated in the fluid if the central hull 1 vibrates only, the field  $p2n$  is that created by the external hull 2 if it only vibrates. The linearity of the equation of Laplace makes it possible to solve independently each problem and then of to superimpose to find the field of pressure total.

The solution of the problem [éq 2.1-1] is, in polar co-ordinates, of the type [bib1]:

$\cos$

$N$   
 $N$

1

$p(R,)$   
 $N$   
=  
+  
or  
ln  
 $Ar$   
 $B$   
 $R$

$\sin N$

One must have  $N \neq 0$ , but if not one with the not-conservation of the volume of the fluid.

*With*

The modal coefficients of added mass  $m_{ijnm}$  are calculated starting from the following formula [R4.07.03] if  $I = 1$  or  $2$ ,  $J = 1$  or  $2$ ,  $(N, m)$  belongs to  $\{2$ .

$m$  *With*

=

$p$

**X**

**im (R)**

**N**

$jn$

**(J) D**

$ijnm$

$J$

$J$

The indexing is a little more complex here than in the formula presented in [R4.07.03]: indices  $I$  and  $J$  refer to hulls 1 and 2, and indices  $m$  and  $N$  are associated the modes of hull. One notice that there is coupling of the modes of the various hulls, external and intern.

It is noticed, on the one hand, that the fluid does not couple the modes of different indices  $N$  bus them integrals

$\cos N \cos m D$

cancel themselves; in addition, the fluid does not couple either the modes

$\cos N$  and  $\sin N$  bus

$\cos N \sin N D =$

0. The only existing coupling is a coupling between

()

two hulls for the modes of comparable nature.

With each mode  $N$ , one associates a matrix of order 4 symmetrical. A submatrix corresponding to projection on mode  $N$  is written:

**FDLV102 - Mass added calculated on a model**

**generalized**

**Summary:**

This test belongs to the field of the fluid interaction/structure, in its aspect inertial coupling: it is about to calculate a matrix of added mass, starting from a generalized model resulting from a calculation by under-structuring

dynamics. One carries out a modal analysis on the fluid coupled system/structure starting from a calculation by under

structuring, and one compares the result with a modal calculation in direct fluid. One tests thus, for a problem

two-dimensional fluid, the possibility of calculating the terms of added car-mass and mass added of coupling between substructures deduced between them by rotation and translation (these “deduced” substructures

not being with a grid).

There is currently only one modeling, which consists in assigning to the fluid grid thermal elements plans.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

Direct modal calculation (without dynamic under-structuring)

#### Calculation of the clean modes in air:

One calculates with the option BANDAGES of operator MODE\_ITER\_SIMULT the first 4 frequencies clean of the system in air (system mass-arises):

mode 1:

vibration of the two cylinders in phase according to OX

mode 2:

vibration of the cylinder n°2 according to OY (on the right)

mode 3:

vibration of the two cylinders in opposition of phase according to OX

mode 4:

vibration of the cylinder n°1 according to OY (on the left)

These modes can be analytically given [bib1].

Calculation ASTER provides for the Eigen frequencies in air:

mode 1:

$$f1 = 17.3555 \text{ Hz}$$

mode 2:

$$f2 = 18.2034 \text{ Hz}$$

mode 3:

$$f3 = 42.6760 \text{ Hz}$$

mode 4:

$$f4 = 57.5418 \text{ Hz}$$

#### Calculation of the matrix of mass added on modal basis:

On this modal basis, one calculates the matrix of added mass of order 4 with the operator CALC\_MATR\_AJOU [U4.55.10] option "MASS\_AJOU" key word MODE\_MECA (terms of the triangular one

inferiors):

$$m11 = 300.67 \text{ kg/m}$$

$$m12 = 0.001 \text{ kg/m}$$

$$m13 = 269.98 \text{ kg/m}$$

$$m14 = 0.009 \text{ kg/m}$$

$$m22 = 269.98 \text{ kg/m}$$

$$m23 = 0.009 \text{ kg/m}$$

$$m24 = 31.05 \text{ kg/m}$$

$$m33 = 301.71 \text{ kg/m}$$

$$m34 = 0.011 \text{ kg/m}$$

$m_{44} = 269.86 \text{ kg/m}$

### **Addition of this matrix to the matrix of generalized mass:**

One adds the matrix thus determined to the matrix of generalized mass (operator COMB\_MATR\_ASSE [U4.53.01]) then one calculates the Eigen frequencies of the structure immersed with

operator MODE\_ITER\_SIMULT option PLUS\_PETITE [U4.52.01].

Calculation finds the Eigen frequencies following:

mode 1:

$f_1 = 15.8782 \text{ Hz}$

mode 2:

$f_2 = 16.7811 \text{ Hz}$

mode 3:

$f_3 = 39.0389 \text{ Hz}$

mode 4:

$f_4 = 53.0488 \text{ Hz}$

#### **5 Recall**

##### **Course of the calculation of mass added by modal synthesis**

- Calcul of the clean modes of substructure 1 (cylinder of left with a grid) with interfaces blocked by MODE\_ITER\_SIMULT [U4.52.02]
- Définition of two dynamic interfaces type CRAIG-BAMPTON (displacement unit imposed):
  - “EAST”: to the point PBLOC2 = L corresponds
  - “CUS”: to the point PBLOC4 = G corresponds
- Définitions of 2 modal bases associated these interfaces: operator DEFI\_INTERF\_DYNA [U4.55.03]:

## BAMO1:

two dynamic modes and a constrained mode: unit displacement

on PBLOC2 = L

## BAMO2:

two dynamic modes and a constrained mode: unit displacement

on PBLOC4 = G

· Définitions of 2 macronutrients associated with these modal bases: operator

MACR\_ELEM\_DYNA

[U4.55.05]

· Définition of the generalized model: operator DEFI\_MODELE\_GENE [U4.55.06]:

Sous\_structure\_1: "CYLINDR0": corresponds to the cylinder of left (with a grid)

Sous\_structure\_2: "CYLINDR1": corresponds to the cylinder of right-hand side (nonwith a grid)

This second substructure is deduced from the first by rotation of  $-90^\circ$ .

ANGL\_NAUT: (- 90. , 0. , 0.)

Connection: "IS" and "CUS"

This definition of the two substructures makes it possible DEFI\_MODELE\_GENE to calculate translation enters the two substructures.

· Création of a profile line of full sky starting from the definite generalized model: operator

NUME\_DDL\_GENE [U4.55.07]

· Assemblage of the matrices of generalized stiffness and mass: operator

ASSE\_MATR\_GENE [U4.55.08]

· Calcul of the matrix of mass added starting from the definite Generalized Model:

The modal bases attached to each of the two substructures define

fields with the nodes of displacement to the site of the 1st substructure in

grid. Operator CALC\_MATR\_AJOU [U4.55.10] transports the field to the nodes

corresponding to the modal base of the second substructure via the translation and

rotation defined higher to assign it to the site of the second substructure

in the grid. The calculation of the added mass is thus carried out following this displacement

of field to the nodes: one can thus calculate the mass added on the 1st substructure,

mass added on the second substructure as well as the term of coupling between

two substructures, taking into account the fluid environment of each one of under

structures.

· Sommutation of the matrix of assembled mass generalized with the matrix of added mass:

COMB\_MATR\_ASSE [U4.53.01]

· Calcul of the clean modes of the immersed total structure: MODE\_ITER\_SIMULT

[U4.52.02].

**FDLV103 - Separate concentric spheres**

**by an incompressible fluid**

**Summary:**

This test relates to the field of the fluids in the aspect inertial coupling. One carries out a modal analysis of one

rigid sphere connected to the solid mass by springs and diving in an incompressible volume of fluid of form

spherical.

The test validates the calculation of mass added in 3D as well as modal calculation for a system fluid-structure

coupled in 3D.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

One bases oneself on an analytical result [bib1]:

In the case of two concentric spheres immersed in the same fluid, it is shown that the mass added induced by the fluid confined on the internal sphere ( $SI$ ) is worth:

3

$R$

$1 + 2 \frac{1}{2}$

2

$R^2$

$m$

=

$R^3$

has

$F$

3

3 1

*R*

1- 1

*R2*

If it is supposed that the sphere has one degree of freedom according to OZ, clean mode of translation sphere (*SI*) according to OZ is given by:

1

2K

*F*

$= 2 m + ma$

5

Numerical application:

$K = 10 \text{ NR/m}$ ,  $m = 12,00 \text{ kg}$ ,  $m = 329,17 \text{ kg}$

*has*

$F = 3.8534 \text{ Hz}$

## 3 Modeling

With

### 3.1

#### Characteristics of modeling

Modeling includes/understands:

· side structure:

2 discrete elements of type K\_TR\_L

(mesh SEG2)

1316 elements of hulls of the type DKT

(mesh TRIA3)

· fluid side:

1316 thermal elements of face of the type 3D

(mesh TRIA3)

14454 thermal elements of volume of the type 3D

(mesh TETRA4)

The nodes of the hull interns are blocked according to all their degrees of freedom of rotation, like their two d.d.l of translation DX and DY (GROUP\_NO: NOINT).

The springs are embedded with the solid mass at the points P1 and P2 (GROUP\_NO: ENCAST).

The hulls are thickness 1 Misters.

## Summary of the results

One finds the values of the analytical results well.

The small variation observed on the added mass can come:

- of a discretization not rather fine of the surface of the sphere,
- or of a discretization not fine enough of fluid volume.

**FDLV104 - Calculation of mass added on model**

**generalized 3D**

**Summary:**

This test of the field of the fluids (fluid coupling/structure) validates the calculation of mass added on a model

generalized of type 3D, namely two spheres coupled by an incompressible fluid.

By a modal analysis carried out by dynamic under-structuring, one obtains the coupled modes of both spheres because of the presence of the fluid. The Eigen frequencies are compared with those determined by one

direct calculation.

One obtains the Eigen frequencies with a margin of less than 3%.

### Reference solution

## 2.1

### Method of calculation used for the reference solution

One uses a direct modal calculation to obtain the Eigen frequencies modified by the fluid around spheres.

The two spheres result by a translation from vector from components (2, 0. , 0.) and for one

rotation of nautical analyses (90. , 0. , 90.) what makes it possible to plan to build a model generalized on the 1st sphere. One will be able to carry out same modal calculation with coupling fluid/structure by using the dynamic under-structuring. **Direct** calculation with taking into account of mass added leads to the Eigen frequencies of the immersed system following:

f1 =

3.1172 Hz

f2 =

3.1183 Hz

f3 =

9.2727 Hz

f4 =

9.8267 Hz

f5 =

22.4400 Hz

f6 =

30.3295 Hz

## **2.2**

### **Results of reference**

Direct modal calculation by Code\_Aster.

## **2.3**

### **Uncertainty on the solution**

Uncertainties on the solution are related to the discretization of the fluid interface/structure and on the invariance of the grid by rotation of nautical angles (90°, 0°, 90°).

Handbook of Validation

#### **4.2 Remarks**

The variation on the two last Eigen frequencies is explained by a not-symmetry of the grid of the fluid interface/structure (thermal) compared to that of the first. **Grid** of the interface fluid/structure (thermal elements) of the second sphere does not result exactly from that from the first by rotation of nautical angles of 90°, 0°, 90°.

#### **Summary of the results**

The results obtained by calculation by dynamic under-structuring show perfect agreement with direct calculation. Nevertheless, to have this agreement, it should be taken care that the grids of the interfaces fluid/structure (thermal elements) of the substructures which are repeated with the interior of the fluid grid result perfectly by rotations of nautical angle defined in

DEFI\_MODELE\_GENE.

***FDLV106 - Calculation of added damping  
in annular flow***

***Summary:***

***This test of the fluid field/structure implements the calculation of mass and damping added on one cylindrical structure subjected to an annular flow which one supposes potential. One calculates in a first***

***times mass and damping added by the flow on the structure for various speeds upstream (4 m/s, 4.24 m/s and 6 m/s), this on a model 3D for the fluid and hull for the structure. The structure has one displacement of rotation around a pivot located at the downstream end of the cylinder compared to the flow.***

*The determined coefficients, one assigns them to a discrete model are equivalent to 1 ddl mass-arise-shock absorber,  
on which one carries out a modal analysis, in order to determine the complex Eigen frequencies of the system  
for the various rates of flow:  
4 m/s: damping,  
4.24 m/s: critical engine failure speed, null damping,  
6 m/s: negative damping, undulation.

Titrate:

FDLV106 Calculation of damping added in annular flow

Date:

12/01/98

Author (S):

**G. ROUSSEAU**

Key:

V8.01.106-A Page:

5/8

The complex Eigen frequencies of this system are written [bib3]:

$R$

2

$= - \pm -$

1

2

$I$

1

or

$K$

$K$

with =

and

=

=

2

$J$

$J$

$I + My$

: reduced damping of the system

: own pulsation.

· Numerical Applications:

One made three calculations of damping added correspondent to three rates of flow which three involve behavior vibratory of the structure:

speed to 4 m/s

speed to 4.24 m/s

speed to 6 m/s

The values of the mechanical system are:

-

$E = 2 \ 1$

. 0 2  $m$

$L = 50\ m$

$R = 1\ m$

$R2 = 11$

,  $m$

$I$

$I = 4\ 5$

. 107  $kg\ m^2$

8

-

$To = 4\ 2$

. 4 10  $N.m\ rad\ S$

1

13

-

$K = 10$

$N.m\ rad\ 1$

The added mass and damping brought by the flow are worth:

$I = 16$

. 6 1010  $kg\ m^2$

has

(independent of the value rate of flow)

According to the speed of entry of the fluid, one a:

-

$V = 4\ m/s$

$C$

8

= -4 00

.

10  $N.m\ rad\ S$

1

0

has

-

$V = 4\ 2$

. 4  $m/s$

$C$

8

= -4 24

.

10  $N.m\ rad\ S$

1

0

*has*

-

$$V = 6 \text{ m/s}$$

*C*

8

$$= -594$$

.

$$10 \text{ N.m rad S}$$

1

0

*has*

Depreciation of the fluid system/structure is written:

.

8

1

$$\text{with } V = 4 \text{ m S}$$

=

-

/

:

$$0 \text{ 24}$$

.

$$10 \text{ N.m rad S}$$

0

The flow does not amplify the vibrations. Structural damping interns is sufficient important to dissipate the energy brought by the flow to the structure.

The system is still deadened.

· with  $V =$ .

*m/s:*

0

$$4 \text{ 24}$$

0 (rate of flow criticizes)

The damping of the system is cancelled.

.

8

1

$$\text{with } V = 6 \text{ m S}$$

= -

-

/

:

$$15$$

$$\cdot 10 \text{ N.m rad S}$$

0  
(the flow amplifies the vibrations)

The damping of the system at this last speed is negative: the system enters then in **instability of undulation**.

## **Summary of the results**

The computational tool of damping under flow (potential assumption) was validated on the mode of rotation of a cylindrical structure subjected to an annular flow. It is however necessary to note [bib1] that the very good agreement enters the semi-analytical model suggested for comparison and calculation numerical is obtained only if the cylinder is sufficiently long.

Indeed, the semi-analytical model is in fact only one approximate solution of the problem arising.

***2***

***Reference solution***

**2.1**  
***Method of calculation used for the reference solution***

*The reference solution is an approximate analytical solution. Analytical fluctuating potentials approached to calculate added rigidity are written [bib1]:*

$$\frac{2}{2}$$

$$R$$

$$\frac{R}{yL} +$$

$$\frac{E}{I^2}$$

$$I(R,y) = \frac{R}{2} + \frac{\sin \sin}{2}$$

$$R - R = \frac{R}{L} \frac{E}{I}$$

$$\frac{2}{2}$$

$$R$$

$$\frac{R}{yL}$$

+

$E$   
 $I$   
 $2$

$2 (R, y)$   
(  
)  
=  
 $R +$   
 $\sin \cos$

$2$   
 $2$   
 $R - R$   
 $R$   
 $L$

$E$   
 $I$

*The rigidity added on the first mode of inflection of the external cylinder considered as a beam rotulé-rotulé is written [bib1]:*

$V 2 3R3$   
 $R2$   
 $K$   
 $0$   
 $E$   
 $I$

*With = -*

$2 ($   
 $R +$   
 $R2 - R$   
 $E$   
 $2$

$E$   
 $I) L$

*Re*

*This rigidity, calculated on a cylindrical geometry, is then assigned to a model with a degree of freedom are equivalent.*

*The system with 1 ddl equivalent is a system mass-arises equivalent to which one affects a mass equalize with the mass of the system increased by the mass added by the fluid and a rigidity equalizes with rigidity of the system increased by the rigidity added by the flow for various speeds.*

*The mass of the system in air is of:*

$$M = 10292 \text{ kg}$$

*for an external cylindrical hull thickness:*

$$C = 2.103 \text{ m}$$

*For equivalent rigidity in air of the system “external hull”, one takes the rigidity of a subjected beam with a force distributed over all its length:*

$$\begin{aligned} F & \\ d3e & \\ K &= 384EI \\ &= 1.649 \cdot 10^{-3} \text{ m} \\ 5L3 & \\ \text{with} & \\ I &= \\ 8 & \end{aligned}$$

$$\text{thus } K = 2.533.104$$

$$\cdot \\ NR/m$$

*The equivalent system coupled with the flow is represented by the following diagram:*

$$\begin{aligned} m & \\ K & \end{aligned}$$

$$\text{with } m = M + M$$

$$K = K + K$$

*With*

*With*

*The own pulsation of the coupled system evolves/moves according to the square rate of flow. If one call  $V_c$  the critical engine failure speed of flow for which rigidity  $K$  is cancelled:*

$$\begin{aligned}
 &2^{nd} \\
 &R - I \\
 &R \text{ l} K \\
 &0 \\
 &V, K + K A (0 \\
 &V) \\
 &2 \\
 &(2 \ 2) \\
 &= 0 \text{ with } 0 \\
 &V \\
 &=
 \end{aligned}$$

$$\begin{aligned}
 &C \\
 &C \\
 &C \\
 &2
 \end{aligned}$$

$$\begin{aligned}
 &I \\
 &R \\
 &3 \ 3
 \end{aligned}$$

$$+$$

$$\begin{aligned}
 &E \\
 &R \\
 &E \\
 &R
 \end{aligned}$$

$$\begin{aligned}
 &E \\
 &R
 \end{aligned}$$

**Summary of the results**

*The variation on the Eigen frequencies increases owing to the fact that when one is close the critical engine failure speed*

*buckling, the rigidity of the equivalent system must tend towards zero. However, with the errors of round (since one assigns “to the hand” the values of rigidity added calculated by the operator to one discrete model) do not make it possible to obtain an own pulsation of the system null at the speed critical.*

*Variations on the added values of rigidity also remain because the reference solution is built on an semi-analytical solution which leaves the approximation according to which the separation of the variables*

*between the dimension  $y$  and the co-ordinates orthoradiales is possible. It will be noticed that the selected potentials*

*to describe the disturbance generated by the vibration of the structure in the fluid do not check the equation of Laplace compète but only in one transverse section of the fluid in co-ordinates orthoradiales. This approximation carried out on the reference solution can explain certain variations with numerical calculation.*

***FDLV108 - Calculation of damping added in  
annular flow (variable density)***

***Summary:***

***This test of the fluid-structure field implements the calculation of mass and damping added on one  
cylindrical structure subjected to an annular flow which one supposes potential. One calculates mass***

*and*

*damping added by the flow on the structure for a speed upstream of 4 m.s<sup>-1</sup>, on a model 3D for the fluid and hull for the structure. The structure has a displacement of rotation around a pivot located at the downstream end of the cylinder compared to the flow. The interest of the test lies in the taking into account of one fluid field of nonhomogeneous density.*

***Summary of the results***

***The computational tool of damping under flow (potential assumption) was validated on the mode of rotation of a cylindrical structure subjected to an annular flow with density variable. It should however be noted [bib1] that the very good agreement enters the semi-analytical model proposed for comparison and numerical calculation is obtained only if the cylinder is sufficiently length, the semi-analytical model being makes of it only one approximate solution of the problem arising.***

***FDLV109 - Calculation of coefficients added in  
plane flow***

**Summary:**

***This test of the fluid field/structure implements the calculation of mass, rigidity and damping added on  
a plane structure subjected to a confined flow which one supposes potential. These added coefficients are  
calculated for a speed upstream of 4 m.s<sup>-1</sup>, on a model 3D for the fluid and hull for the structure.  
structure is subjected to an imposed displacement of inflection.***

### ***Summary of the results***

*The computational tool of coefficients added under flow (potential assumption) was validated on the first two modes of inflection of a plane structure. It should however be noted [bib1] that the very maid agreement between the semi-analytical model suggested for comparison and numerical calculation is not obtained that if the plate is sufficiently long, the semi-analytical model being does only one of them approximate solution of the problem arising.*

***FDLV110 - Calculation of mass added on modes  
obtained by under-structuring***

***Summary:***

***This test of the field of the modal analysis and the interaction fluid-structure implements the calculation of mass added on a structure made up of three concentric cylinders separated by two rings from fluid (water) which one supposes the behavior governed by the potential theory (fluid true, incompressible at rest). model is three-dimensional for water. The structure is represented by elements of the mean hull type in modeling A (the structure is rigid in the reference solution). This one is characterized by two clean modes evaluated by dynamic under-structuring, with interface of the type CRAIG-BAMPTON. The interest of the test lies in the use of the functionality `NOEUD\_DOUBLE` of the operator `CALC\_MATR\_AJOU`.***

***This functionality makes it possible to calculate the effects of added mass of a structure represented by a grid surface (without thickness) which is bathed in a fluid. The fluids chosen in this case-test are of densities different on both sides from the intermediate cylinder (water at different temperatures).***

### **Reference solution**

*One calculates the clean modes of the system after having checked those of each substructure. One evaluate then the mass added on the modes in air.*

### **2.1**

#### **Decomposition in substructures**

**First substructure: roll intermediate**

*The first substructure is consisted of the intermediate cylinder and four springs of stiffness  $k_2 = 107 \text{ N.m}^{-1}$ . These springs are embedded with the interface with the external cylinder which constitutes second substructure (interface of the type CRAIG-BAMPTON).*

*IH*  
 *$k_2$*

*Mass cylinder 1:  $m_1 = 2.041 \text{ } 10^6 \text{ kg}$*

*The cylinder being rigid, its movement can be modelled by a system mass-arises with a degree of freedom:*

*$m_1$*

*Achacune of its ends, the cylinder is connected to two springs in parallel: equivalent stiffness of each one =  $2k_2$  is  $k'$*

*1*  
 *$2k$*   
*1*  
 *$4k$*

*The Eigen frequency is worth then:*

*2*  
 *$F =$*

## ***1.4 Conditions initial***

***The displacement of the piston is null at the initial moment and the fluid is at rest.***

## ***2 Reference solution***

***The solution must show the absorption of an acoustic wave by absorbing surface. The movement piston is a uniform translation according to the x axis. Taking into account the symmetry of the problem***

***around this axis, one will obtain an identical field of pressure in all the plans  $X = \text{Cte}$ . Moreover, the absorbing border is orthogonal with this axis. One thus studies the absorption of waves of pressure***

***plane under normal incidence. The theory [bib1] known as that with a fluid paraxial border of order 1, this absorption is perfect. It is what one must check with this reference solution.***

***One thus goes, by observing the evolution of the pressure in a given point of the grid, to stick to to find in the signal obtained the duration of excitation and the return at rest after the passage of the wave, characteristic of its absorption.***

**4/10****2.1*****Results of reference***

*One gives in this paragraph the results obtained with Code\_Aster in this configuration. One check that they are satisfactory and one takes them as reference for the future.*

*They concern, for the case 3D, the evolution of pressure in a point of the fluid located at 150 m of the piston*

*in direction X and in the center of the section in the yz plan. For the case 2D, the point is located at 40 m*

*piston according to X and in the middle of the section in the direction y (in 2D, one takes a shorter grid*

*and refined).*

***Pressure in the fluid - case 3D******8,00E+03******6,00E+03******4,00E+03******2,00E+03******0,00E+00******0,00E+00******5,00E-01******1,00E+00******1,50E+00******2,00E+00******2,50E+00******-2,00E+03******Pressure (Pa)******-4,00E+03******-6,00E+03******-8,00E+03******Time (S)******Pressure in the fluid - case 2D******5,00E+03******4,00E+03******3,00E+03******2,00E+03******1,00E+03******0,00E+00******-1,00E+03******0,00E+00***

**-3,00E+03**  
**-4,00E+03**  
**-5,00E+03**  
**Time (S)**

*As envisaged, the width of the signal measured in both cases is identical to that of the function of excitation. Physically, one observes well compression due to advanced piston, then depression corresponding to its retreat to return to its initial position. One notes also clearly the return at rest immediately after the passage of the wave and the absence of signal thought of the end of the grid.*

**Summary of the results**

**One finds by calculation with two modelings qualitatively, the maximum ones of pressure with good moments and the return at rest after the passage of the wave.**

**The results obtained with operators DYNA\_LINE\_TRAN and DYNA\_NON\_LINE are very close.**

**The difference comes from obtaining to each step in time from the state from balance from the efforts from the second**

**member with operator DYNA\_NON\_LINE. This difference remains however tiny because the step of time used with DYNA\_LINE\_TRAN is sufficiently small.**

***1.3***

***Boundary conditions and loading***

***1.3.1 Conditions of Dirichlet***

***The loading defined here is of the displacement type imposed on a surface. More precisely, one consider that the bottom of the tank can move only according to direction X.***

***According to this direction X, one will request the system by imposing on the bottom of the tank a displacement***

***sinusoidal in time, of frequency 1,7704 Hz and amplitude 0,001 Mr.***

*This imposed displacement can be compared to a request of the mono-support type applied by base tank (seismic application).*

### **1.3.2 Conditions of Neumann**

*In superposition in the surface condition of Dirichlet previously defined, one subjects also it model with the field of gravity (imposed voluminal effort).*

*Lastly, the upper surface of the fluid field is seen characterized by conditions of the type surfaces free.*

**:**

**V8.03.100-A Page:**

**4/8**

**2**

**Reference solution**

**2.1**

**Method of calculation used for the reference solution**

*The only results of the literature [bib1] are modal types: Eigen frequencies and paces of certain modes.*

*Being given the need for testing operator DYNA\_NON\_LINE, and being given relative complexity model which is 3D, it is not possible to find the Eigen frequencies by transitory analysis in a reasonable time CPU.*

*For information, this type of analysis carried out with a random loading corresponding to a noise*

*white requires, for reasons of probabilistic convergence, a calculation for a physical time of loading of 250 S, which corresponds to a time CPU of a few hours.*

*In order to have a computing time about a few minutes, it is obligatory to calculate the evolution over a time runs (a few seconds). This restrictive framework does not make it possible to find precisely and in a way compatible with a postprocessing automated the results of modal analysis. The validation brought by this test can thus be only of the type not regression of the solution numerical.*

*As the functionalities of calculation coupled fluid-structure are the subject already of a certain number of tests of validation in addition, this limitation with nonthe regression for this particular case-test is not crippling.*

*As complementary validation, complete calculation with signal of 250 S.A. carried out. spectra at the points of observations indeed showed a good agreement with the results of modal analysis of [bib1].*

## 2.2

### *Results of reference*

*One tests values of displacements at various moments, according to direction X, for two points of grid: N145 and N3119. These points are on the free face, on both sides of the wall deformable, as one can see it on the diagram of the paragraph [§1.1].*

## 2.3

### *Uncertainty on the solution*

*Numerical solution (calculated with version 7.03.06 of the code).*

## 2.4 Reference

***Summary:***

*Calculation in fluid coupling accoustics-structure of the first mode of a system fluide1 - piston fluid 2.  
One tests the matrices of rigidity and mass of the elements of the fluid type and type coupling fluid-structure.*

*One tests also the boundary condition of the free face type.*

*Fourteen modelings are tested.*

***Reference solution***

***2.1***

***Method of calculation used for the reference solution***

*At the low frequencies, the wavelengths acoustic of the movements considered are large compared to dimension characteristic of fluid volume ( $L/C \ll$ )*

*1. The problem is thus*

*monodimensional according to axis X.*

*It is shown [bib1] that a light fluid as the air primarily acts like an added stiffness tandis that a heavy fluid behaves only like one added mass. One can thus calculate first Eigen frequency of the system:*

*S*

*K*

*K = K*

*2*

*air =*

*=*

*C*

*has has*

*with*

*L*

*m*

*has*

*m = m<sub>s</sub> + m<sub>e</sub> = L S*

*S*

*S*

*+ L S*

*E*

*E*

*Maybe,*

*c<sup>2</sup>*

*=*

*has has*

*(the L*

*S S + L*

*E E)*

**Note:**

*The first own pulsation of the system checks L/C well  $\ll 1$ .*

### **Summary of the results**

The value of the modal frequency obtained with Code\_Aster is satisfactory since, with one moderated discretization, it is equal to 0,01% close with the theoretical solution, whatever the type of modeling.

**ADLV101 - Modes of shaking of a tank  
filled of water**

**Summary:**

This test, of the acoustic and fluid field, relates to the research of the Eigen frequencies of a tank rectangular filled of a fluid including/understanding a free face. The modal analysis determines the first thus

modes of shaking of the surface of the fluid filling the tank. The first three Eigen frequencies are found with less than 1% of the analytically calculated frequencies.

## **Problem of reference**

### **1.1 Geometry**

free face

H

L

L

dimensions of the tank:

height:  $H = 0.3 \text{ m}$

length:  $L = 0.8 \text{ m}$

width:  $L = 0.1 \text{ m}$

### **1.2**

## **Properties of materials**

The modelled material is the fluid contained in the tank:

density:  $C = 1000 \text{ kg/m}^3$

speed of sound:  $C = 1400 \text{ m/s}$

### **1.3**

## **Boundary conditions and loading**

One imposes the field of gravity on the whole of the fluid model

charge = AFFE\_CHAR\_MECA

**2**

## **Reference solution**

### **2.1**

## Method of calculation used for the reference solution

The reference [bib3] provides the general formula of the modes of shaking in a tank parallelepipedic:

2  
2

2

2

1

*I*

*J*

*I*

*J*

$F =$

$G$

+

$HT H$

+

$ij$

2

$L^2$

$l^2$

$L^2$

$L$

2

where *I* and *J* are the orders of the longitudinal and transverse modes (a number of nodal lines in each direction).

In the particular case or - *L* is large, the formula is simplified for the longitudinal modes [bib1],

$L$

[bib2].

**2.2**

## Results of reference

$L$

For

= 8. and  $H = 0.3$

. the first four modes are at frequencies 0.898, 1.384, 1.709 and 1.975.

$L$

**Summary of the results**

Modeling A implements elements of fluid of the type HEXA8 and elements of surface free of type QUAD4. The result obtained reveals a maximum error of 1.52% compared to analytical solution.

Modeling B utilizes elements of fluid of the type HEXA20 and elements of surface free of type QUAD8. The results correlate perfectly with the analytical solution.

Elements fluid of the type HEXA27 and fluid weighing of type QUAD9 are used for modeling C. the results obtained are identical to the reference solution.

Modeling D makes it possible to validate elements fluid of the type PENTA6 and elements of surface free of type TRIA3. The results obtained reveal a relative error of 1.479% compared to the reference solution.

Modeling E makes it possible to validate the elements of free face of type TRIA6. They are connected to elements of fluid of the type PENTA15. There is perfect coincidence of the results with the solution analytical.

Generally, it is observed that the results obtained by elements with interpolation quadratic (HEXA20, HEXA27) are in excellent agreement with the analytical results. Nevertheless the elements with linear interpolation have an acceptable precision on the results.

***Handbook of Validation***

***V8.21 booklet: Accoustics***

***Document: V8.21.102***

***ADLS102 - Meridian oscillator fluidelastic***

***Summary:***

***The objective is to calculate the displacement of the piston of a “oscillator meridian fluid-rubber band”.***

***It is about piston-arises coupled with a fluid contained in a channel with rigid and fixed walls; the channel is crossed by a wave of depressurisation.***

***One considers the plane problem of this meridian model. This two-dimensional problem is brought back to a problem***

***monodimensional by considering by approximation that rates of transverse flow induced by movement of the piston are transmitted instantaneously in axial speeds.***

***Only one modeling is used. The calculation of the modes is in formulation  $U, p$ .***

Elements 2D are thus used; these elements are based on meshes QUAD4 for the fluid and for piston, on meshes SEG2 for the interface between fluid and piston to take into account the fluid interaction

structure (PHENOMENE= 'MECANIQUE', MODELISATION='2D\_FLUI\_STRU').

The boundary conditions of nonreturn of the wave are carried out by modelling a piston shock absorber with each

end; the excitation is carried out by applying a depression to the piston of entry.

The fluid which one considers is water (hot), the model schematizing the interaction fluid-structure in annular space between tank and envelope of heart during a fast depressurisation.

An exact analytical solution exists. Its comparison with the results produced by *Code\_Aster* allows to validate the taking into account of the fluid coupling structure in 2D.

***1.1 Geometry***

*One describes below the model of meridian oscillator fluidelastic schematizing the interaction fluid-structure in annular space tank-envelope of heart.*

*The meridian elastic fluid oscillator is a model of annular space tank-envelope of heart of engine; it consists of an oscillator (piston side-arises appearing a mobile wall) coupled with a compressible fluid contained in a channel with rigid and fixed walls.*

*The channel is crossed by a wave of depressurisation.*

*The figure [Figure 1.1-a] below illustrates the model described.*

*H*

*Z*

*E*

*D X*

*Appear 1.1-a: Total diagram of the oscillator meridian fluid-rubber band*

*The channel is of section rectangular of dimensions  $E \times H$  the rigid side piston moves according to  $Z$  perpendicular to a wall.*

*A wave of depressurisation arrives by the left; while moving towards the line (without possibility of return) this wave aspires the piston which, by its resulting displacement, generates waves propagating towards the ends of the conduit, supposed infinitely long so that there is no reflexion.*

*One conceives a two-dimensional modeling of this system, represented with the figure [Figure 1.1-b] below:*

*K*

*2L*

*2*

*Reference solution*

*2.1*

*Method of calculation used for the reference solution*

*The goal is to determine temporal displacement  $Z(T)$  of the piston of wall.*

*One considers the plane problem of this meridian model of which geometrical characteristics, mechanics and fluids are described on the figure [Figure 1.1-a]; the side piston is length  $2L$ .*

*The two-dimensional problem is brought back to a monodimensional problem while considering by approximation that rates of transverse flow  $z$  & induced by the movement of the piston transmit instantaneously in axial speeds in the channel.*

*In the volume of control  $D = \int dx$  of wide  $dx$  under the piston of wall one can write:*

*$D(V) = \int dx$*

*2nd*

*& $z$*

*In the fluid variation speed and variation of pressure in adiabatic evolution are connected by:*

*$P = cV$*

*The pressure at the moment  $T$  in a point of X-coordinate  $X$  results from the superposition of the*

*propagation from*

*all elementary sources distributed on the piston:*

*The coupling thus consists of this: the movement of the piston of acceleration  $\ddot{z}(T)$  induced in the channel one*

*field of pressure  $P(X, T)$  whose effort resulting on the extent from the piston itself acts as return on dynamics of the oscillator.*

*The geometrical, mechanical characteristics and fluids of the model are presented on the figure [Figure 1.1-b].*

*It is considered initially that the piston and the fluid are at rest and one carries out to release oscillator with*

*the moment  $T = 0$  by imposing an initial speed to him.*

*The expression of the pressure  $P(X, T)$  in a point of the channel develops:*

$C T X$

$X - U$

$+ L$

$U - X$

$P(X, T) =$

-

+

Result of modeling

4.1 Values

tested

The results of calculation with Code\_Aster are presented graphically on [Figure 4.1-a] in superposition with the “analytical” reference solution.

The curve of Code\_Aster appears very close to the reference during the first 4 oscillations but the differences, at the same time in amplitude and phase, are increasingly perceptible when  $T$  increases.

***FDLL200 - Piping embedded and free by beam  
fluid-structure***

***Summary:***

*The objective is to calculate the low frequency behavior of a piping filled with water. Piping has a circular section; it is embedded at an end and free other side.*

*One uses the elements of beam élasto-acoustics available in Code\_Aster which take into account the fluid interaction structure (PHENOMENON = “MECHANICAL”, MODELING = “FLUI\_STRU”).*

*The boundary conditions are mechanical to simulate the embedding of the structure, and acoustics for to simulate the condition of tank of the fluid in this point (boundary conditions of null pressure and potential of fluid displacement no one).*

*The fluid which one considers is a heavy fluid in order to put forward the phenomenon of coupling enters the column of fluid and the structure constitutive of piping. Properties of the fluid and material of structure are selected so that the celerity of a wave being propagated in the fluid is the same one as celerity of a mechanical wave being propagated in piping. Under these conditions, first mode of structure resounds at the same frequency as the column of fluid.*

*An exact analytical solution exists which provides the first Eigen frequency. Its comparison with results produced by Code\_Aster (search for eigenvalues) makes it possible to validate the taking into account of fluid coupling structure in the longitudinal direction, the transverse effects being non-existent in this model.*

*One tests thus partially the matrix of stiffness and that of mass.*

**2**

***Reference solution***

**2.1**

***Method of calculation used for the reference solution***

***One studies the vibratory behavior of a piping filled with fluid. Piping is embedded with one of its ends and free at the other end. The section of piping is circular. One be interested in the low frequencies of the longitudinal behavior of piping.***

***One defines:***

***length of the tube:***

***L,***

***Young modulus of the pipe:***

***E,***

***diameter external of the pipe:***

***D,***

***thickness of the walls:***

***ep,***

***surface of the solid section:***

***Ss,***

***surface of the fluid section:***

***Sf***

***celerity in the pipe (structure):***

***Cs,***

***celerity in the fluid:***

***cf,***

*One chose the characteristics of the fluid and the pipe in order to have the following relation:*

$$\begin{aligned} E \\ C = C = \\ = C = 1000 \text{ m/s} \end{aligned}$$

*F*  
*S*

*S*

*In this particular case of equality of celerities, one shows [bib2] that the first Eigen frequency of coupled problem is such as:*

*L*

$$\begin{aligned} Ss \\ E \\ tg \\ = \\ . \end{aligned}$$

$$\begin{aligned} 2 \\ C \\ S \\ S \\ F \\ C \\ F \end{aligned}$$

*It is worth in this case:  $F = 157,94 \text{ Hz}$*

## *2.2 Results of reference*

*Only one modeling is used. The calculation of the modes is in formulation U, p.*

## *2.3 Uncertainty of the solution*

*Analytical solution.*

## ***AHLV100 - Guide wave at anechoic exit***

### ***Summary:***

*A rectilinear guide of wave at anechoic exit, with rigid walls, whose propagation medium is air “normal”, is excited by a harmonically vibrating piston.*

*One calculates by an acoustic formulation the acoustic field of pressure of the harmonic response for 13 different modelings. The results are tested in 2 points at the entry and 2 points at the exit.*

*They make it possible to validate the matrices of rigidity, mass, damping (impedance), the vector source (imposed normal speed) as well as the operators of postprocessings.*

*The results of reference come from an analytical calculation.*

## **Summary of the results**

Modelings give the awaited results. It will be noted however that times CPU are appreciably more important than those mentioned in the cards of validation AHLV100 of the 11/8/95 (V8.22.100 Document).

In modelings using of the tetrahedrons or the triangles, the distribution of the pressure is less uniform than in the other cases following the non-uniformity of the grid.

**AHLV101 - Guide wave at anechoic exit**

**Summary:**

A rectilinear guide of wave at anechoic exit, with rigid walls, whose propagation medium is air “normal”, is excited by a harmonic incidental wave, normal with the face of entry. One calculates the field of

acoustic pressure of the harmonic response by using the élasto-acoustics formulation in pressure-displacement-potential of displacements.

The tests relate to 3 different modelings (finite elements élasto-acoustics three-dimensional, two-dimensional and axisymmetric), they make it possible to validate the matrices of rigidity, mass, impedance and vector source for 3 modelings.

The result of reference comes from an analytical calculation.

## Reference solution

### 2.1

#### Method of calculation used for the reference solution

The frequencies of the excitation are rather low and jointly the guide of wave is sufficiently length compared to its side dimensions so that one limits oneself to the plane waves: the phenomenon is then identical in all points of a plan of wave, i.e. does not depend on the co-ordinates describing points of this plan, y and Z for example.

One gives on this assumption the well-known general solution of the equations of accoustics for

the two sizes **pressure**  $p$  and **acoustic speed**  $v$ :

$$X$$

$$X$$

$$v = F T -$$

$$G$$

$$T$$

**éq 2.1-1**

$$C +$$

$$+$$

$$C$$

$$X$$

$$X$$

$$p = C F T -$$

$$G$$

$$T$$

**éq 2.1-2**

$$C -$$

$$+$$

$$C$$

The guide is supposed to be closed at the end of X-coordinate  $L$  on an impedance  $ZL$ ; there is one reflexion on the level of this impedance, which gives a wave of return  $G$ .

In each point of the guide, there is then superposition of the two functions  $F$  and  $G$ ; by definition even final impedance  $ZL$  imposes on the point of X-coordinate  $L$ , between  $p$  and the  $v$  relation.

$$pL = Z$$

$$v$$

$$L$$

$L$   
 In the harmonic case  $F$  and  $G$  are written:  
 $X$

$X$   
 $IT$

$FT -$   
 $IE$   
 $C$

$C =$   
 $X$

$X$   
 $It +$

$GT +$   
 $RE$   
 $C$

$C =$   
 where  $I$  and  $R$  are determined by the boundary conditions.

$p$   
 In the calculation of the impedance  $Z =$   
 in any item  $X$  the variable time this time is eliminated,  
 $v$   
 in accordance with the calculation even of the impedances and is written:

$X$   
 $X$   
 $- I$   
 $I$   
 $($   
 $IE$

$C - R E C$

$Z X) = Z 0$

$X$

$X$

$- I$

$I$

$I E$

$C + R E C$

Handbook of Validation

V8.22 booklet: Harmonic accoustics

HP-51/96/094 - Ind A

---

**Code\_Aster** ®

Version

4.0

Titrate:

AHLV101 Guides wave at anechoic exit

Date:

12/01/98

Author (S):

**F. STIFKENS, G. ROUSSEAU**

Key:

V8.22.101-A Page:

4/12

The final impedance becomes:

$L$

$L$

$- I$

$I$

$I E$

$C - R E C$

$Z = Z$

$L$

0

$L$

$L$

$- I$

$I$

$I E$

$C + R E C$

One calls  $Z = C$

0

iterative impedance.

On the fluid border at the entry of the guide the condition limits of incidental wave type imposed on

$P$

$P$  I.E.(internal excitation)  $T$

=

$I$

0

, is obtained by writing at the border the following linear relation:

$p - C v = P$

$N$

$I$

**éq 2.1-3**

where  $v =$

$N$

$\mathbf{v} \cdot \mathbf{N}$  is the speed according to unit normal  $\mathbf{N}$  **outgoing** of the fluid.

One imposes moreover on the exit of the guide a value of final impedance  $Z = Z$

$L$

0 which does one of them

anechoic end.

The final impedance is equal to the iterative impedance  $Z_0$  when  $R = 0$ , i.e. when there is not no the wave of return; one then has a pure travelling wave in the direction of the incidental wave, that is to say:

$X$

$I T$

$C$

$v = I E$

$X$

$I T$

$C$

$p = C I E$

thus the relation of imposed incidental wave [éq 2.1-3] is written:

$p v = ($

$p$

$= )$

$0 + ( = )$

$0 = 2$

$I$

$C$

$X$   
 $cv\ X$   
 $C\ IE\ T$   
 $N$   
 $I\ T$   
from where 2 are identified

$C\ IE$   
=  $pi$ ; one deduces the expression from it from the travelling wave of pressure in  
guide when one imposes  $pi$  on the entry of the guide:

$X$   
 $X$   
 $P -$   
 $P$   
 $I\ T$   
 $I$   
 $I$   
0

$C$   
 $p =$   
 $E$   
 $C =$   
 $E$   
2  
2

## **Summary of the results**

The discretization is strong since it is approximately 45 nodes by wavelength. This is why us let us obtain results of a high precision: pressure calculated by Code\_Aster at the point it less favorable differs from the theoretical value from less than 1%.

It should be also noted that all modelings used give identical results.

**Document: V9.01.100**

**SZLZ100 - Tire on an eccentric cycle**

**Summary:**

The purpose of this test is calculation of the damage starting from a history of loading in constraints, then of a history of loading in deformations.

Starting from a simple history of loading defined by DEFI\_FONCTION [U4.21.02], one extracts the cycles elementary by the method of counting of cycles of the RCCM [R7.04.01], then one calculates the damage

elementary associated each cycle, by interpolation on the curve of Wöhler of material (if history of loading in constraints and by interpolation on the curve of Manson-Whetstone sheath of material) (if history of loading in deformations).

The curve of Wöhler is defined by DEFI\_FONCTION [U4.21.02]. The interpolation is of logarithmic curve type on

the number of cycles to the rupture NR and on the alternate constraint Salt.

The curve of Manson-Whetstone sheath is also defined by DEFI\_FONCTION.

To finish, one determines the total damage undergone by the part by cumulating all the elementary damage by

linear rule To mine.

In this test, one also checks the taking into account of the value of the average constraint on the calculation of

elementary damage by the method of Wöhler. The first calculation is carried out without correction, a second

with a correction To stack and the third with a correction of Goodman.

On this simple example, the extraction of the elementary cycles and the calculation of the damage can be made

manually, by applying the algorithms presented in the reference document [R7.04.01].

The results provided by operator POST\_FATIGUE [U4.67.01] are of this fact very satisfactory.

## **Problem of reference**

### **1.1 Geometry**

The analysis consists in determining the damage undergone by a part in a point to which one provides the history of loading.

To test the calculation of the damage by the method of Wöhler, one considers the history of loading in constraints and one extracts the elementary cycles by a method of counting of cycles, which is in this test method of the RCCM. Then one calculates the elementary damage due to each elementary cycle, by interpolation on the curve of Wöhler of material.

The curve of Wöhler is found in the form of a function point by point, which gives the value of

a number of cycles to the rupture according to the alternate constraint  $Salt =$

.

2

The interpolation is of logarithmic curve type on the X-coordinate and the ordinate and one authorizes to prolong

linearly this function on the right and on the left.

Three different calls to operator POST\_FATIGUE [U4.67.01] make it possible to take account or not of the average constraint of each elementary cycle.

The adopted correction is that of the diagram of Haigh, either according to the line of Goodman or according to

the parabola To stack [R7.04.01].

One determines the total damage by the linear rule of office plurality To mine.

To test the calculation of the damage by the method of Manson-Whetstone sheath, one considers the history of

loading in deformations and one extracts the elementary cycles by a method of counting of cycles, which is in this test the method of the RCCM. Then one calculates the elementary damage due to each elementary cycle, by interpolation on the curve of Manson-Whetstone sheath of material. The curve of Manson-Whetstone sheath is provided in the form of a function point by point, which gives the value

number of cycles to the rupture according to

.

2

One determines the total damage by the linear rule of office plurality To mine.

## **SZLZ101 - Calculation of the damage/Method RAINFLOW**

### **Summary:**

The purpose of this test is calculation of the damage starting from a history of loading in constraints. Starting from a simple history of loading defined by DEFI\_FONCTION [U4.21.02], one extracts the cycles

elementary by the method of counting of cycles of the RAINFLOW [R7.04.01], then one calculates the damage

elementary associated each cycle, by interpolation on the curve of Wöhler of material.

One tests various possibilities of introducing the curve of Wöhler, as well as the taking into account of the coefficient of

elastoplastic concentration.

To finish, one determines the total damage undergone by the part by cumulating all the elementary damage by

linear rule To mine.

This example is a test of validation of software POSTDAM developed by Department REME, provided in

the handbook of validation of version 1.0 of this software.

The results provided by operator POST\_FATIGUE [U4.67.01] are completely identical to those provided by

software POSTDAM.

## **Problem of reference**

### **1.1 Geometry**

The analysis consists in determining the damage undergone by a part in a point to which one provides the history

of loading in constraints.

Starting from a simple history of loading defined by DEF<sub>I</sub>\_FONCTION [U4.21.02], one extracts them elementary cycles by the method of counting of cycles of RAINFLOW [R7.04.01], then one calculates elementary damage associated each cycle, by interpolation on the curve of Wöhler of material.

One tests various possibilities of introducing the curve of Wöhler and the taking into account or not of one

elastoplastic coefficient of concentration:

· The curve of Wöhler is defined in the form:

*S*

= alternate constraint = 1 2

=

*alt*

(*E E*

*C*

)

*X*

*LOG10 (Salt)*

2

3

1 *NR* if  $S \geq S$

0 + 1

+ 2

+

*NR*

*has*

*has*

*X*

*has*

*X*

*a3 X*

*alt*

$I$  $= 10$  $D = 0.$ 

if not

with:

 $EC.$  = Young Modulus associated with the curve with tiredness with material, $E$  = Young Modulus used to determine the constraints,constants of the material  $a_0$ ,  $a_1$ ,  $a_2$  and  $a_3$ ,and  $IF$  limit of endurance of material.

· The curve of Wöhler is defined in the same form and moreover one takes account of a coefficient of elastoplastic concentration defined by:

 $K = 1.$ 

if

 $< 3S$  $E$  $m$  $K = 1 + (1 - N)/3$  $-1 /$  $-1$ 

if

 $3$  $< <$  $E$  $($  $Sm$  $) ((Nm))$  $S$  $3 m S$  $m$  $m$  $K = 1 N$ 

if

 $3m S$  $<$  $E$  $m$ 

where

 $Sm$  is the acceptable maximum constraint,and  $N$  and  $m$  two constants depending on material.

.

The curve of Wöhler is defined in the analytical form of Basquin: **D = A Salt**

To finish, one determines the total damage undergone by the part by cumulating all the damage elementary by the linear rule To mine.

**SZLZ102 - Tire with various methods of counting**

**Summary:**

This test relates to the methods of countings of cycles (RAINFLOW, RCCM) starting from a history of loading in constraints.

Starting from a simple history of loading defined by DEFI\_FONCTION [U4.21.02], one extracts the cycles

elementary by the method of counting of cycles of the RAINFLOW [R7.04.01], then by the method of counting of cycles RCCM [R7.04.01].

One also tests the taking into account of the coefficient of stress concentration KT.

This example is a test of validation of software POSTDAM developed by Department REME, provided in

the Handbook of Validation of version 1.0 of this software.

The results provided by operator POST\_FATIGUE [U4.67.01] are completely identical to those provided by

software POSTDAM.

***Handbook of Validation***

***V9.01 booklet: Tire***

***Document: V9.01.105***

***SZLZ105 - Counting of cycles by RAINFLOW  
and calculation of the damage***

***Summary:***

***Transitory linear elastic problem quasi-static in mechanics of the structures.***

***Calculation of the final damage in an element subjected to a cyclic loading, with an elastic behavior linear.***

***A modeling in plane constraints and a modeling in 3D.***

***This test validates the method of counting of cycles (RAINFLOW) established in operator CALC\_FATIGUE [U4.67.01] as well as the method of calculation of the damage in imposed constraint (curve of Wöhler) or imposed deformation (curve of Manson-Whetstone sheath). The reference solution is an analytical solution.***

***It also validates the calculation of the constraints and equivalent deformations using the options EQUI\_ELGA\_SIGM, EQUI\_ELNO\_SIGM, EQUI\_ELGA\_EPSI, EQUI\_ELNO\_EPSI, EQUI\_ELGA\_EPME and EQUI\_ELNO\_EPME.***

**SZLZ106 - Tire under random request**

**Summary:**

*The purpose of this test is calculation of the damage starting from a random request which is characterized by its spectral moments.*

*From the spectral moments of the random loading one determines the average damage undergone by the structure*

*[R7.04.02].*

*With this intention one has two methods of counting of cycles of constraints:*

- method of counting of the peaks of constraints,*
- method of the goings beyond of a given level.*

*One tests also various possibilities of introduction the curve of Wöhler as well as the taking into account of*

*elastoplastic coefficient of concentration  $K_e$ .*

*The results of reference of this test are the values provided by software POSTDAM developed by Department REME (EDF-DER-EP).*

*The results provided by operator POST\_FATI\_ALEA [U4.67.05] are completely identical to those provided by*

*software POSTDAM.*

**Problem of reference**

**The analysis consists in determining the average damage undergone by a part subjected to a loading random.**

**Loading of the random type is entirely characterized by the values of the spectral moments of order 0, 2 and 4: 0, 2 and 4 which is introduced under key words *MOMENT\_SPEC\_0*, *MOMENT\_SPEC\_2* and *MOMENT\_SPEC\_4*.**

**For the calculation of the damage it is necessary to choose a method of counting among the two available ones in**

**Code\_Aster:**

- method of counting of the peaks of constraints,**
- method of counting of going beyond of a given level.**

**It is necessary moreover introduce the curve of Wöhler of the material which can be defined in three forms**

**distinct mathematics:**

- function point by point, which gives the value of the number of cycles to the rupture, according to the alternate constraint Salt,**
- 

**analytical form of Basquin:  $D = A S$**

**alt**

- analytical form “current zone”**

### **SZLZ107 - Criteria of tiredness of CROSSLAND and DANG VAN-PAPADOPOULOS**

#### **Summary:**

The purpose of this test is calculation of the criteria of CROSSLAND and DANG VAN-PAPADOPOULOS.

Starting from a periodic and radial multiaxial loading, one calculates the value of the criterion of CROSSLAND, then

value of the criterion of DANG VAN-PAPADOPOULOS.

The loading being radial the values of the two criteria must be identical.

This test results from the thesis of I. PAPADOPOULOS "Tires polycyclic metals: a new approach" and corresponds to a test of Gough-Pollard [bib1].

The results provided by operator POST\_FATIGUE [U4.67.01] are completely satisfactory.

## 2

### Reference solution

#### 2.1

#### Method of calculation used for the reference solution

The results of reference result from the thesis of I. PAPADOPOULOS [bib1]. For the criterion of **CROSSLAND**, one can also obtain them manually.

The loading being radial the two criteria must provide the same results.

#### 2.2

#### Results of Reference

For the **criterion of CROSSLAND**, one tests the value of the amplitude of cission, the value of the pressure

hydrostatic maximum and the value of the criterion:

= 313.579 MPa

= 137. MPa

=

*has*

*P*

*Rcrit*

8.281

max

-

For the **criterion of DANG VAN-PAPADOPOULOS**, one tests the value of the ray of the smallest sphere

circumscribed with the loading, the value of the maximum hydrostatic pressure and the value of the criterion:

$$K^* = 313.579 \text{ MPa}$$

$P$

$$= 137. \text{ MPa}$$

$R_{crit} =$

max

**SZLZ108 - Damage by the methods of TAHERI  
("TAHERI\_MANSION" and "TAHERI\_MIXTE")**

**Summary:**

The purpose of this test is calculation of the damage starting from a history of purely uniaxial loading in deformations by methods "TAHERI\_MANSION" or "TAHERI\_MIXTE".

The methods of Taheri apply only to loadings in deformations and do not allow

contrary to the method of Manson-Whetstone sheath to hold account about appearance of the cycles of constraints.

Handbook of Validation

2/6

**1**

**Problem of reference**

The analysis consists in determining the damage undergone by a structure subjected to a history of

loading in deformations. One uses the method of Rainflow to determine the number of cycles elementary and its half amplitude of each cycle.

For the loadings considered, the method of Rainflow determines 5 cycles of half amplitude:

1  
2  
3  
4  
5  
= 0.2  
.5,  
= 0.2  
.5,  
= 0.7  
.5,  
= 0.2  
.5 and  
= 17  
.5 .

2  
2  
2  
2  
2

Then one calculates the damage undergone by the structure by the method of TAHERI\_MANSON and the method

TAHERI\_MIXTE.

As long as the amplitude of deformations of the various cycles applied to the structure remains increasing

1 2

...

$N$

, the methods of TAHERI\_MANSON and TAHERI\_MIXTE are identical to

2  
2  
2

method of MANSON\_COFFIN (calculation of the number of cycles to the rupture,  $N_{rupt}$ , by interpolation on

the curve of Manson-Whetstone sheath and calculation of the damage by 1  $NR$

).

$rupt$

*I**i-I*

On the other hand if a cycle *I* presents a half amplitude lower than

, methods of

2

2

Taheri differ from the method of Manson-Whetstone sheath.

.

*I*

The method of “TAHERI\_MANSON” consists in determining an amplitude of constraint with

2

*I*

to leave

and

2

max (maximum value of the half amplitude of deformation met before cycle *I*).

With this intention, the user must provide a tablecloth

,

2

2

max under the operand  
TAHERI\_NAPPE.

\*

*I**I*

From

, one determines a half amplitude of deformations  
using a function

2

2

introduced under operand TAHERI\_FONC. The value of the elementary damage of cycle *I*, is  
\*<sub>i</sub>

determined by interpolation of  
on the curve of Manson\_Coffin.

2

· For method “TAHERI\_MIXTE”, one proceeds in the same way for the determination of the half

*I*

amplitude of constraint

, then one determines the value of the elementary damage of cycle *I*

2

*I*

by interpolation of

on the curve of Wöhler.

2

This method thus requires the data of the curves of Wöhler and Manson\_Coffin.

One determines the total damage by linear office plurality of the elementary damage.

**Handbook of Validation**

**V9.01 booklet: Tire**

**Document: V9.01.109**

**SZLZ109 - Damage of Lemaitre**

**in postprocessing**

**Summary:**

The purpose of this test is calculation of the damage of “LEMAITRE” starting from a history of multiaxial loading

unspecified and of the history of the cumulated plastic deformation.

The damage is calculated

(

$D(T)$  starting from the data of the tensor of the constraints ( $T$ ) and the formation

figure cumulated (

$p(T)$  in every moment  $T_i$  (provided by the user). Moreover, one calculates the total damage

$NR$

$D = ($

$D(T_i).$

$i=1$

The characteristics material  $E$  (Young modulus), (Poisson's ratio) and  $S$  (parameter of material)

must depend on the temperature  $T$  ( $T$

$(T)$  must thus be provided by the user at the same moments as

$(T)$  and

(

$p(T)$ )).

## **1 Problem of reference**

*One calculates the damage  $D(T)$  starting from the data of the tensor of the constraints ( $T$ ) and of cumulated plastic deformation  $p(T)$  resulting from a calculation in thermomechanics. The kinetics of damage is given by:*

$S$

$1$

$D \& =$

$$1 (+) 2$$

$$+ 3$$

$$1$$

$$eq$$

$$(1- 2 ) 2$$

$$H p$$

$$if$$

$$\&$$

$$p > p$$

$$($$

$$D$$

$$1 - D) 2s 3ES$$

$$2ES$$

$$D = 0$$

$$if not$$

*is the equivalent constraint of von Mises*

*eq*

*is the hydrostatic constraint*

*H*

*p represents the threshold of damage*

*D*

*S is a characteristic of the material (MPa)*

*S is a characteristic of material*

*NR*

*One also calculates the total damage  $D = D (T.$*

*I)*

*i=1*

**2****Reference solution****2.1****Method of calculation used for the reference solution**

*The reference solution is generated starting from option POST\_FATIGUE. Adopted methodology consist in defining a history of loading in constraints and to recover the evolution of cumulated plastic deformation associated starting from a tensile test 3D in thermo-viscoplasticity.*

*The history of loading (T) and p (T) is then used in a calculation POST\_FATIGUE with parameters materials presented at the paragraph [§1.1] to define a reference solution.*

**2.2****Results of Reference**

*The result of reference of the damage of Lemaître is obtained for a tensile test to deformation imposed and on constant temperature. The state of stresses and cumulated plastic deformation resulting of this test are as follows:*

**Constraint****Cumulated plastic deformation****Time [S]****Sxx (T) [Pa]****P (T)**

***SZLZ111 - Damage of Lemaître-Sermage  
in postprocessing POST\_FATIGUE***

***Summary:***

*The purpose of this test is calculation of the damage of Lemaître-Sermage “LEMAITRE” starting from a history of unspecified multiaxial loading and of the history of the cumulated plastic deformation.*

*One calculates the damage starting from the data of the tensor of the constraints and the plastic deformation cumulated in every moment  $T_i$  (provided by the user). Moreover, one calculates the cumulated damage.*

*The characteristics material  $E$  (Young modulus), (Poisson's ratio) and  $S$  (parameter of material) must depend on the temperature  $T$ . This one must thus be provided by the user at the same moments as  $(T)$  and  $p(T)$ .*

*Pd = 0.02*

*1.1.1 Modeling*  
*With*

*In this modeling, one checks the calculation of the damage of Lemaître-Sermage compared to reference solution given in [V9.01.109]. Values of the exhibitor  $S$  and  $S$  in the expression of the damage of generalized Lemaître are worth:*

*$S = 1.0$  and  $S = 7.0$*

### ***1.1.2 Modeling***

***B***

*In this second modeling, one checks the calculation of the damage of Lemaître-Sermage per report/ratio*

*with an analytical solution obtained by applying the algorithms presented in the document of reference [R7.04.01]. Values of the exhibitor  $S$  and  $S$  in the expression of the damage of Generalized Lemaître are worth:*

*$S = 1.003$  and  $S = 7.0$*
